Cataloging-in-Publication data can be accessed via the Library of Congress Online Catalog. Library of Congress Control Number: 2024950261

ISBN-13: 978-1-64792-216-0 (two-volume hardcover set)
ISBN-13: 978-1-64792-225-2 (PDF ebook)
ISBN-13: 978-1-64792-226-9 (epub)

The paper used in this publication meets the minimum requirements of American National Standard for Information Sciences—Permanence of Paper for Printed Library Materials, ANSI Z39.48–1984.

CONTENTS

— VOLUME 1 —

List of Abbreviations xxxiii
Preface xxxv

INTRODUCTION

Christof Rapp

1. Who Was Aristotle? xxxvii

2. The *Complete Works* of Aristotle: What Is Included and How the Collection Came About xxxix

   2.1. Not Everything Is Included in the *Corpus Aristotelicum* xl
   2.2. The *Corpus Aristotelicum* Includes More Than It Should xlii
   2.3. Some Works Might Have Been Differently Arranged xliv
   2.4. The Composition of the *Corpus Aristotelicum*: Hints and Guesses xlv
   2.5. Bekker's Edition of the *Corpus Aristotelicum* xlvii
   2.6. Writings That Did Not Make It into Bekker's Edition xlix

3. Aristotle's Philosophical Oeuvre: A Survey lii

   3.1. The Works Traditionally Assigned to the *Organon* liii
   3.2. The *Physics* and the Foundations of the Study of Nature lvii
   3.3. The Study of Nature: Aristotle's Grand Plan and How It Is Executed lix
   3.4. The Study of the Soul and of the Psychic Functions That the Soul Accomplishes Together with the Body lxi
   3.5. Transition: The Studies of the Soul and of Animals as Intertwined lxiv
   3.6. The Zoological Works lxv
   3.7. Theoretical Wisdom or Primary Philosophy lxix
   3.8. The Science of Human Affairs: Ethics and Politics lxxiii
   3.9. From Ethics to Moral Psychology lxxvi
   3.10. The Two Remaining Projects: Rhetoric and Poetics lxxvii

CATEGORIES

S. Marc Cohen 1

1 Homonymy, Synonymy, and Paronymy • 2 Said-of-a-Subject versus in-a-Subject • 3 Said-of-a-Subject • 4 The Ten Categories • 5 Substance • 6 Quantity • 7 Relatives • 8 Quality • 9 Doing, Being Affected, and the Rest of the Categories • 10 Opposites • 11 Contraries • 12 Priority • 13 Simultaneity • 14 Forms of Movement • 15 Having

De Interpretatione

Francesco Ademollo and Paolo Fait 29

1 Introduction • 2 The Name • 3 The Verb • 4 The Saying • 5 Assertoric Sayings: One and Many, Simple and Compound • 6 Affirmation, Negation, and Contradiction • 7 Universal and Particular Things; Universal, Non-universal, and Particular Assertions • 8 The Unity of Affirmations and Negations • 9 Assertions about Future Particular Events • 10 Affirmations and Negations with Indefinite Names and Verbs • 11 Single and Multiple Affirmations and Negations • 12 Modal Affirmations and Negations • 13 The Table of the Possible, the Admissible, the Impossible, and the Necessary • 14 Contrary Beliefs and Sayings

Prior Analytics

Robin Smith 49

Book 1

1.1 Subject and Scope; Key Terms Defined • 1.2 Conversions of Non-modal Premises • 1.3 Conversions of Necessary and Possible Premises • 1.4 Deductions in the First Figure • 1.5 Deductions in the Second Figure • 1.6 Deductions in the Third Figure • 1.7 More on Deductions; All Deductions Reduce to the First Figure • 1.8 Deductions with Two Necessary Premises • 1.9 Deductions with One Necessary Premise in the First Figure • 1.10 Deductions with One Necessary Premise in the Second Figure • 1.11 Deductions with One Necessary Premise in the Third Figure • 1.12 Some Results about Deductions with Necessary Premises • 1.13 Conversion of Possible Premises; Definition of Possible • 1.14 Deductions with Two Possible Premises in the First Figure • 1.15 First Figure: One Possible and One Non-modal Premise • 1.16 First Figure: One Necessary and One Possible Premise • 1.17 Second Figure: Two Possible Premises • 1.18 Second Figure: One Possible and One Non-modal Premise • 1.19 Second Figure: One Necessary and One Possible Premise • 1.20 Third Figure: Two Possible Premises • 1.21 Third Figure: One Possible and One Non-modal Premise • 1.22 Third Figure: One Necessary and One Possible Premise • 1.23 All Deductions Whatever Can Be Reduced to the First Figure • 1.24 Some General Results about Deductions • 1.25 Further Results about Extended Deductions • 1.26 Which Problems Are Easiest to Prove and Which Hardest • 1.27 How to Find Deductions: Selecting Premises • 1.28 Finding Premises from Which to Deduce a Given Conclusion • 1.29 Deduction by Deduction to the Impossible • 1.30 This Method Is the Universal Method for Any Subject • 1.31 Comparison with the Method of Division • 1.32 Reducing All Deductions to the Deductions in the Figures • 1.33 Misleading Appearance of Deduction Because of Position of Terms • 1.34 Misleading Appearances of Deduction Because of Setting-Out • 1.35 Setting-Out a Term without a Name • 1.36 Alternative Ways Premises May Be Expressed • 1.37 A Note on the Many Senses of "Belongs to" • 1.38 Reduplicated Terms in Premises • 1.39 Use

Names Rather Than Accounts in Premises • 1.40 A Note on "Good" and "the Good" • 1.41 Issues concerning "Belongs"; No Absurdity from Setting-Out • 1.42 Not All the Conclusions in the Same Deduction Are through a Single Figure • 1.43 On Deductions Attacking a Definition • 1.44 Arguments from an Assumption Not to Be Reduced • 1.45 Reducing Deductions from One Figure to Those in Another • 1.46 "Not to Be This" and "to Be Not This" Distinguished

Book 2

2.1 Additional Conclusions That Follow in Deductions • 2.2 True Conclusions from False Premises: First Figure • 2.3 True Conclusions from False Premises: Second Figure • 2.4 True Conclusions from False Premises: Third Figure • 2.5 Circular or Reciprocal Proof: First Figure • 2.6 Circular or Reciprocal Proof: Second Figure • 2.7 Circular or Reciprocal Proof: Third Figure • 2.8 Converting Deductions: First Figure • 2.9 Converting Deductions: Second Figure • 2.10 Converting Deductions: Third Figure • 2.11 Deduction through the Impossible: First Figure • 2.12 Deduction through the Impossible: Second Figure • 2.13 Deduction through the Impossible: Third Figure • 2.14 Comparison of Probative and Through-the-impossible Demonstration • 2.15 Deductions from Opposite Premises • 2.16 Asking for the Initial Thing • 2.17 "Falsehood Not Because of This" • 2.18 The Cause of a False Conclusion • 2.19 Watch for the Repeated Term When Debating • 2.20 When There Is, or Is Not, a Refutation • 2.21 Being Misled by Inconsistent Suppositions • 2.22 On the Conversion of Terms • 2.23 The Figures Apply in Rhetoric and Everywhere Else • 2.24 Paradigms • 2.25 Abduction • 2.26 Objections • 2.27 Likelihoods and Signs

Posterior Analytics

C. D. C. Reeve 141

Book 1

1.1 Prerequisites for Scientific Knowledge • 1.2 Unconditional Scientific Knowledge • 1.3 Regresses and Circles • 1.4 In Every Case, Intrinsically, and Universally • 1.5 Three Errors about Universal Demonstration • 1.6 Scientific Premises Are Intrinsic Ones • 1.7 Demonstration Stays within a Single Kind • 1.8 Demonstration Is of Eternal Things • 1.9 Special and Indemonstrable Starting-Points • 1.10 The Starting-Points in a Kind • 1.11 Platonic Forms; Common Things • 1.12 The Role of Questioning in Science • 1.13 The That and the Why • 1.14 The Superiority of the First Figure • 1.15 Negative Propositions • 1.16 Ignorance and Error in Immediate Cases • 1.17 Error in Non-immediate Cases • 1.18 Perceptual Ignorance • 1.19 The Number of Premises and the Sorts of Predication • 1.20 Fixed Extremes and Unlimited Middles • 1.21 Privative Demonstrations Come to a Stop • 1.22 When Either Extreme Is Fixed, Affirmative Premises Must Be Limited • 1.23 Two Corollaries • 1.24 The Superiority of Universal Demonstration • 1.25 Superiority

of Probative Demonstration • 1.26 Superiority of Direct Demonstration • 1.27 The Relative Exactness of Sciences • 1.28 The Unity of a Science • 1.29 Multiple Demonstrations of the Same Thing • 1.30 No Demonstration of What Happens by Luck • 1.31 No Demonstration through Perception • 1.32 Not All Deductions Can Have the Same Starting-Points • 1.33 Scientific Knowledge and Belief • 1.34 Acumen

Book 2

2.1 The Four Scientific Questions • 2.2 The Search for a Middle Term • 2.3 Relations between Definitions and Demonstrations • 2.4 Proving a Definition • 2.5 Definition and Division • 2.6 Other Failed Attempts to Deduce a Definition • 2.7 Proving Definitions • 2.8 Reinvestigation of Definition and Demonstration of the What-It-Is • 2.9 Making Clear What Something Is through Demonstration • 2.10 The Different Sorts of Definition • 2.11 The Four Causes as Middle Terms • 2.12 Causes and Effects • 2.13 Division and Definitions • 2.14 Division and Problems • 2.15 Problems with the Same Middle Terms • 2.16 Relations between Causes and Effects • 2.17 Can One Thing Have Several Causes? • 2.18 The True Cause Is the Closest One to the Thing • 2.19 How We Get a Grasp on Scientific Starting-Points

Topics

C. D. C. Reeve 207

Book 1

1.1 Aim of the Study • 1.2 Usefulness of the Study • 1.3 What It Is to Possess the Methodical Inquiry • 1.4 What the Methodical Inquiry Is Based On • 1.5 What a Definition, a Special Affection, a Kind, and a Coincident Are • 1.6 No Universal Methodical Inquiry • 1.7 The Number of Ways in Which Things Are Said to Be the Same • 1.8 Basis for the Proposed Division of Predicates • 1.9 The Categories of Predicates • 1.10 Dialectical Premises • 1.11 Dialectical Problems • 1.12 Deduction and Induction • 1.13 The Four Instruments • 1.14 (1) Getting Hold of Premises • 1.15 (2) Distinguishing in How Many Ways Something Is Said of Things • 1.16 (3) Finding Differences • 1.17 (4) Seeing Similarities • 1.18 Usefulness of the Last Three Instruments

Book 2

2.1 Issues Concerning Problems • 2.2 Various Topics • 2.3 Topics Relating to Things Said in Many Ways • 2.4 Additional Topics • 2.5 A Sophistical Topic and Others • 2.6 Additional Topics • 2.7 Contraries • 2.8 The Four Sorts of Opposition • 2.9 Co-ordinates and Inflections • 2.10 Similarity • 2.11 Addition and Unconditional versus Conditional Predications

Book 3

3.1 Relative Choiceworthiness (1) • 3.2 Relative Choiceworthiness (2) • 3.3 Relative Choiceworthiness (3) • 3.4 Unconditional Choiceworthiness • 3.5 More and Greater • 3.6 Particular Predications

Book 4

4.1 Kinds, Forms, and Special Affections • 4.2 Kinds, Forms, and Differences • 4.3 Contraries, Inflections, and Co-ordinates • 4.4 Additional Topics • 4.5 Additional Topics • 4.6 Additional Topics

Book 5

5.1 Sorts of Special Affections • 5.2 The Correct Assignment of a Special Affection (1) • 5.3 The Correct Assignment of a Special Affection (2) • 5.4 Whether an Affection Assigned as Special Is in Fact Special (1) • 5.5 Whether an Affection Assigned as Special Is in Fact Special (2) • 5.6 Opposites • 5.7 Inflections and Similarity of Relations • 5.8 The More and the Less and Similarity of Degree • 5.9 Capacities and Superlatives

Book 6

6.1 Definitions • 6.2 Non-perspicuously Expressed Definitions • 6.3 Definitions Involving Superfluous Material • 6.4 Whether a Definition Defines an Essence • 6.5 Kind • 6.6 Difference • 6.7 The More and the Less • 6.8 Definitions of Relatives • 6.9 State and Privation, Relatives, and Opposites • 6.10 Inflections, Forms, Homonyms, Synonyms, Things Said in Many Ways • 6.11 Complexes, Composites, and Substitution of Names • 6.12 Errors in Definitions • 6.13 Compound Definitions • 6.14 Recapitulation and Conclusion

Book 7

7.1 Sameness and Distinctness • 7.2 Sameness and Definition (1) • 7.3 Sameness and Definition (2) • 7.4 The Handiest Topics • 7.5 Establishing versus Disestablishing a Definition

Book 8

8.1 How to Ask Dialectical Questions (1) • 8.2 How to Ask Dialectical Questions (2) • 8.3 Hypotheses Difficult to Attack • 8.4 How to Answer Dialectical Questions (1) • 8.5 How to Answer Dialectical Questions (2) • 8.6 How to Answer Dialectical Questions (3) • 8.7 Answering Questions That Lack Perspicuousness or Are Said in Many Ways • 8.8 Answering Particular versus Universal Questions; Haggling • 8.9 Practicing on Oneself; Unacceptable Hypotheses • 8.10 Resolving Arguments That Deduce a Falsehood • 8.11 Criticism of Arguments as Such versus When Framed as Questions • 8.12 Clear and False Arguments • 8.13 Asking for What Was Initially at Issue; Asking for Contraries • 8.14 Training and Practice in Dialectical Arguments

Sophistical Refutations

Sophistici Elenchi

C. D. C. Reeve 341

1 Apparent Deductions and Apparent Refutations • 2 Didactic, Dialectical, Examinational, and Contentious Arguments • 3 Aims of Competitors and Rivals • 4 Modes of Refutation Depending on Speech • 5 Fallacies Depending on the Coincident • 6 Fallacies Based on Ignorance of What a Refutation Is • 7 Sources of Deception in Fallacies • 8 Sophistical Refutations • 9 The Nature of Dialectic • 10 Arguments against the Name versus against the Thought • 11 The Examinational Craft • 12 False and Unacceptable Things • 13 Babbling • 14 Solecisms • 15 How to Question Effectively • 16 How to Answer Effectively • 17 Acceptable Resolutions versus True Ones • 18 Correct Resolutions • 19 Arguments Depending on Homonymy and Ambiguity • 20 Arguments Depending on Composition and Division • 21 Arguments Depending on Accentuation • 22 Arguments Depending on Things Said in the Same Way That Are Not the Same • 23 Arguments Depending on Speech • 24 Arguments Depending on the Coincident • 25 Arguments Depending on Strict and Unconditional versus in Some Respect • 26 Arguments Depending on the Definition of a Refutation • 27 Arguments Depending on Asking for What Was Initially at Issue • 28 Arguments Depending on Affirming the Consequent • 29 Arguments Depending on an Addition • 30 Arguments Depending on Making Many Questions into One • 31 Arguments Depending on Babbling • 32 Arguments Depending on Solecisms • 33 Simpleminded versus Incisive Arguments • 34 Originality of the Study

Physics

C. D. C. Reeve 391

Book 1

1.1 Scope and Method of Natural Science • 1.2 Natural Science's Starting-Points; Parmenides and Melissus • 1.3 Refutation of Parmenides and Melissus • 1.4 The Views of the Natural Scientists • 1.5 The Starting-Points Are Contraries • 1.6 The Number of Starting-Points (1) • 1.7 The Number of Starting-Points (2): Our Own Account • 1.8 A Puzzle of the Ancient Thinkers Solved • 1.9 More on Starting-Points

Book 2

2.1 What Nature Is and What It Is to Be by Nature • 2.2 Natural Science Distinguished from Mathematics and First Philosophy • 2.3 What Sorts of Causes There Are and in What Way They Are Causes • 2.4 Luck and Chance as

Causes • 2.5 How Luck and Chance Are Causes • 2.6 Luck and Chance Defined and Distinguished • 2.7 The Natural Scientist Must Know All Four Causes • 2.8 Does Nature Act for an End? • 2.9 The Necessity in Natural Things

Book 3

3.1 Movement (1) • 3.2 Movement (2) • 3.3 Mover and Moved • 3.4 The Unlimited • 3.5 Pythagoreans and Platonists on the Unlimited • 3.6 The Way the Unlimited Exists • 3.7 The Various Sorts of Unlimited; Matter • 3.8 Refutation of Arguments for the Actually Unlimited

Book 4

4.1 The Existence of Place • 4.2 Is Place Matter or Form? • 4.3 Can a Thing Be in Itself or a Place in a Place? • 4.4 What Place Is • 4.5 Puzzles about Place Solved • 4.6 Views about the Void • 4.7 What a Void Is; Refutation of Arguments for the Existence of a Void • 4.8 No Void Separate from Bodies, or Occupied by a Body • 4.9 No Void in Bodies • 4.10 Puzzles and Views about Time • 4.11 What Time Is; the Now • 4.12 Various Affections of Time; What It Is to Be in Time • 4.13 What Now, at Some Time, Just, Recently, Long Ago, and Suddenly Are • 4.14 Before in Time; Time and the Soul

Book 5

5.1 Classification of Movements and Changes • 5.2 Classification of Intrinsic Movements; Immovability • 5.3 Together, Separate, Making Contact, Intermediate, Successive, Contiguous, and Continuous • 5.4 What It Is for a Movement to Be One in Kind, in Form, or Unconditionally • 5.5 Contrariety of Movement • 5.6 Contrariety of Movement and Rest

Book 6

6.1 Every Continuum Consists of Continuous and Divisible Parts (1) • 6.2 Every Continuum Consists of Continuous and Divisible Parts (2) • 6.3 The Now Is Indivisible and Nothing Is in Movement or at Rest in It • 6.4 Modes of Divisibility • 6.5 Issues Concerning Change (1) • 6.6 Issues Concerning Change (2) • 6.7 The Limitedness or Unlimitedness of Movement, Magnitude, and of What Is Moved • 6.8 Rest and Coming to Rest • 6.9 Arguments against the Possibility of Movement • 6.10 The Movement of What Is without Parts; No Change Is Unlimited

Book 7

7.1 The Need for a Primary Mover • 7.2 The Primary Mover Is Always Together with What Is Moved by It • 7.3 Everything That Is Altered Is Altered Due to Perceptibles • 7.4 A Puzzle Concerning the Commensurability of Movements • 7.5 Proportionality of Movements

Book 8

8.1 The Eternality of Movement • 8.2 Puzzles about the Eternality of Movement • 8.3 Immobility and Movement • 8.4 Whatever Is in Movement Is Moved by Something • 8.5 The Primary Mover Is Immovable • 8.6 The

Primary Mover Is One and Eternal • 8.7 Spatial Movement Is the Primary Sort of Movement • 8.8 Only Circular Spatial Movement Can Be Continuous (1) • 8.9 Only Circular Spatial Movement Can Be Continuous (2) • 8.10 The Primary Mover

Appendix

7.3 (Alternate Text)

De Caelo

On the Heavens

C. D. C. Reeve 553

Book 1

1.1 The Completeness of the Universe • 1.2 Primary Body (Ether) • 1.3 Primary Body Is Exempt from Alteration and Passing Away • 1.4 Circular Movement Has No Contrary • 1.5 Primary Body Is Not Unlimited • 1.6 No Element Is Unlimited • 1.7 No Body Is Unlimited • 1.8 There Cannot Be More Than One Heaven (1) • 1.9 There Cannot Be More Than One Heaven (2) • 1.10 The Cosmos Is Incapable of Coming to Be or Passing Away (1) • 1.11 Ways in Which Things Are Incapable of Coming to Be or Passing Away • 1.12 The Cosmos Is Incapable of Coming to Be or Passing Away (2)

Book 2

2.1 Corroboration from Ancient Views • 2.2 Up and Down, Left and Right • 2.3 Why There Are Several Spatial Movements in the Heaven • 2.4 Why the Shape of the Heaven Must Be Spherical • 2.5 Why the Primary Heaven Revolves in One Direction Rather Than the Other • 2.6 Why the Primary Heaven's Movement Is Regular Rather Than Irregular • 2.7 The Stars • 2.8 The Stars' Spatial Movement • 2.9 No Harmony of the Spheres • 2.10 The Stars' Order • 2.11 The Stars' Shape • 2.12 Two Puzzles about the Stars' Movements • 2.13 The Earth (1) • 2.14 The Earth (2)

Book 3

3.1 Summary of Previous Books and of Previous Views on Coming to Be • 3.2 Every Simple Body Has a Natural Movement; How Non-natural Movement Occurs • 3.3 The Nature of an Element • 3.4 The Number of Elements; Atomism Refuted • 3.5 There Is More Than One Element • 3.6 Elements Are Not Eternal but Come to Be from Each Other • 3.7 How Elements Come to Be from Each Other; the Views of Empedocles and Plato Refuted • 3.8 Elements Are Not Differentiated by Their Shape

Book 4

4.1 Heavy and Light • 4.2 Examination of Previous Views • 4.3 The Movement of Heavy and Light Bodies • 4.4 The Differences of Heavy and Light Bodies • 4.5 The Way in Which the Matter Is One • 4.6 Shapes and Movements of Bodies

On Coming to Be and Passing Away

De Generatione et Corruptione

C. D. C. Reeve 641

Book 1

1.1 Coming to Be, Passing Away, Growth, Withering, and Alteration • 1.2 Unlimited Divisibility of Magnitudes • 1.3 Unconditional Coming to Be • 1.4 Alteration • 1.5 Growth • 1.6 Contact • 1.7 Affecting and Being Affected (1) • 1.8 Affecting and Being Affected (2) • 1.9 Affecting and Being Affected (3): Potentially versus Actually • 1.10 Mixing

Book 2

2.1 The Elements of bodies (Earth, Water, Air, Fire) and Their Matter • 2.2 The Primary Contrarieties: Hot and Cold, Dry and Wet • 2.3 The Contrarieties and the Elements • 2.4 The Change of the Elements into Each Other • 2.5 Ways in Which the Elements Change into Each Other • 2.6 Against Empedocles • 2.7 How the Simple Bodies Mix to Form Compound Ones • 2.8 Each Element Is Present in Every Compound • 2.9 Material, Formal, and Final Causes of Coming to Be and Passing Away • 2.10 Efficient Cause of Coming to Be and Passing Away: The Sun's Movements • 2.11 Necessity in the Sphere of Coming to Be and Passing Away

Meteorology

Malcolm Wilson and C. D. C. Reeve 687

Book 1

1.1 Scope of the Inquiry • 1.2 Introduction to the Material and Efficient Causes • 1.3 An Inquiry into the More Appropriate Causes • 1.4 Fiery Celestial Phenomena • 1.5 The Aurora • 1.6 Comets (1) • 1.7 Comets (2) • 1.8 The Milky Way • 1.9 The Effects of the Wet Exhalation: Precipitation • 1.10 Dew and Frost • 1.11 Correspondences between Rain/Snow and Dew/Frost • 1.12 Hail • 1.13 Rivers • 1.14 Land-Sea Exchange

Book 2

2.1 Whether the Sea Has Springs • 2.2 Views on the Origin of the Sea • 2.3 Salinity of the Sea • 2.4 The Material Cause of Winds • 2.5 The Efficient Cause of Winds • 2.6 Catalog of the Winds • 2.7 Previous Views on Earthquakes • 2.8 Aristotle's Theory of Earthquakes • 2.9 Thunder and Lightning

Book 3

3.1 Tornadoes and Fire-Tornadoes • 3.2 Phenomena of Reflection • 3.3 The Halo • 3.4 Rainbows • 3.5 The Geometry of Rainbows • 3.6 Parhelia and Rods; Metals and Minerals

Book 4

4.1 Hot, Cold, Wet, and Dry; Putrefaction • 4.2 Concoction and Unconcoction • 4.3 The Various Sorts of Concoction • 4.4 Wet and Dry • 4.5 Bodies and Solidification • 4.6 The Various Sorts of Solidification • 4.7 Coarse-Grainedness Caused by Heat and Caused by Cold • 4.8 The Capacities and Incapacities of Uniform Bodies (1) • 4.9 The Capacities and Incapacities of Uniform Bodies (2) • 4.10 Uniform Bodies • 4.11 Hot and Cold Liquids and Solids • 4.12 Transition to Biology

De Anima

On the Soul

C. D. C. Reeve 775

Book 1

1.1 Inquiry about the Soul • 1.2 Movement, Perception, Incorporeality • 1.3 Soul as a Starting-Point of Movement • 1.4 Soul as a Harmony and as a Self-Moving Number • 1.5 Soul as Composed of Elements

Book 2

2.1 First Definition of Soul • 2.2 Second Definition of Soul • 2.3 The Capacities of Soul • 2.4 The Nutritive Capacity • 2.5 Perception • 2.6 Perceptible Objects • 2.7 Sight and Its Objects • 2.8 Hearing and Its Objects • 2.9 Smell and Its Objects • 2.10 Taste and Its Objects • 2.11 Touch and Its Objects • 2.12 Perception as the Capacity to Receive Form without Matter

Book 3

3.1 Why There Are No More Than Five Perceptual Modalities • 3.2 Perceiving That We Perceive; Relation of Perceptual Modalities to Their Objects; Distinguishing These Objects • 3.3 Imagination • 3.4 Passive Understanding • 3.5 Productive Understanding • 3.6 Simple and Complex Intelligible Objects • 3.7 Active and Potential Scientific Knowledge • 3.8 Scientific

Knowledge, Perception, and Imagination • 3.9 Soul as a Cause of Movement • 3.10 Understanding, Imagination, and Desire as Causes of Animal Movement • 3.11 Causes of Animal Movement • 3.12 Interrelations of the Soul's Capacities (1) • 3.13 Interrelations of the Soul's Capacities (2)

De Sensu et Sensibilibus

On Perception and Perceptible Objects

Klaus Corcilius 835

1 Introduction • 2 Composition of the Perceptual Organs: The Eye • 3 Sight and Color • 4 Flavor • 5 Smell and Odor • 6 Puzzles about Perceptible Objects • 7 Perceiving More Than One Object at the Same Time

On Memory and Recollection

Klaus Corcilius 857

1 Definition and Explanation of Memory • 2 Definition and Explanation of Recollection

On Sleep and Waking

De Somno et Vigilia

Klaus Corcilius 865

1 Introduction • 2 Why Sleeping and Waking Occur • 3 The Efficient Cause of Sleep

On Dreams

De Insomnis

Klaus Corcilius 875

1 To Which Part of the Soul Does Dreaming Belong? • 2 The Subject of Dreaming • 3 The Efficient Cause of Dreaming

On Prophecy during Sleep

De Divinatione per Somnum

Klaus Corcilius 883

1 Is Prophecy during Sleep Possible? • 2 The Explanations

On Length and Shortness of Life

De Longitudine et Brevitate Vitae

Andrea Falcon 887

1 Puzzles about Longevity • 2 Modes of Destruction • 3 A Puzzle • 4 Failed Correlations and Trans-generic Facts • 5 Length and Shortness of Life in Animals Explained • 6 Relative Length and Shortness of Life in Animals and Plants Explained

On Youth and Old Age, Life and Death, and Breathing

De Juventute et Senectute, de Vita et Morte, de Respiratione

Andrea Falcon 893

1 The Nutritive and the Perceptual Soul and Their Relation to the Body • 2 The Central Location of the Nutritive and the Perceptual Soul • 3 Additional Arguments for the Central Location of the Nutritive and the Perceptual Soul • 4 Additional Considerations for the Central Location of the Soul • 5 Vital Heat and the Ways in Which It Is Destroyed • 6 Vital Heat and the Need for Its Regulation in Plants and Animals • 7 (1) A Few Facts about Breathing • 8 (2) Democritus, Anaxagoras, and Diogenes of Apollonia on Breathing (1) • 9 (3) Anaxagoras and Diogenes of Apollonia on Breathing (2) • 10 (4) Democritus on Breathing • 11 (5) Plato on Breathing • 12 (6) Respiration and Nutrition • 13 (7) Empedocles on Breathing • 14 (8) Why All Animals Need to Control Their Bodily Temperature • 15 (9) Insects and Other Bloodless Animals • 16 (10) Blooded Animals • 17 (11) Blooded Animals Continued • 18 (12) Cetaceans • 19 (13) Cooling Explained • 20 (14) Empedocles on Why Animals Dwell in Water • 21 (15) Breathing Explained • 22 (16) The Relation of the Heart to the Lung and the Gills • 23 (17) Natural Death • 24 (18) A Few Definitions • 25 (19) Suffocation Explained • 26 (20) Palpitation and Pulsation • 27 (21) The Mechanics of Breathing Explained

On the History of Animals

C. D. C. Reeve 917

Book 1

1.1 Parts of Animals and How They Differ; Forms and Kinds; Differences in Animals: Lives, Actions, Characters, and Parts • 1.2 Parts for Nourishment and Excretion • 1.3 Parts for the Emission of Seed • 1.4 Liquid in Animals: Blood and Blood Vessel • 1.5 Live-Bearing, Egg-Laying, and Larvae-Generating

Animals: Feet, Fins, and Wings • 1.6 Kinds of Animals; Simple Forms • 1.7 The Cranium • 1.8 Forehead and Face • 1.9 Eyebrows and Eyes (1) • 1.10 Eyes (2) • 1.11 Ears, Nose, and Tongue • 1.12 Neck, Thorax, Breasts, and Nipples • 1.13 The Abdomen and Its (Male) Parts • 1.14 Other Parts • 1.15 Trunk and Limbs; Perceptual Parts • 1.16 The Internal Parts • 1.17 Heart and Viscera

Book 2

2.1 Differences between the Animals, Their Parts, and Their Movements • 2.2 The Teeth of Dogs • 2.3 The Teeth of Horses • 2.4 Wisdom Teeth • 2.5 The Teeth of Elephants • 2.6 The Tongue of Elephants • 2.7 The Size of Mouths • 2.8 The Apes (1) • 2.9 The Apes (2) • 2.10 The Blooded Egg-Laying Four-Footed Animals • 2.11 The Chameleon • 2.12 The Birds • 2.13 The Fishes • 2.14 The Snakes • 2.15 The Internal Parts of the Blooded Animals • 2.16 The Kidneys and the Bladder • 2.17 The Position of the Heart

Book 3

3.1 The Parts Involved in Generation • 3.2 The Blood Vessels (1) • 3.3 The Blood Vessels (2) • 3.4 The Blood Vessels (3) • 3.5 The Sinews • 3.6 The Fibers • 3.7 The Bones • 3.8 Cartilage • 3.9 Nails, Hooves, Claws, Horns, and Beaks • 3.10 Hair (1) • 3.11 Hair (2) and Skin • 3.12 Changes of Color • 3.13 Membrane • 3.14 The Omentum • 3.15 The Bladder • 3.16 Flesh • 3.17 Fat and Suet (1) • 3.18 Fat and Suet (2) • 3.19 Blood and Serum • 3.20 Marrow and Milk (1) • 3.21 Rennet and Milk (2) • 3.22 Seed

Book 4

4.1 Bloodless Animals: Soft-Bodied Animals • 4.2 Soft-Shelled Animals • 4.3 Crabs • 4.4 Testaceans • 4.5 Urchins • 4.6 Sea Squirts • 4.7 Insects • 4.8 Perceptual Modalities • 4.9 Voices and Voiced Sounds • 4.10 Sleeping and Waking • 4.11 Sex

Book 5

5.1 Generation of Animals • 5.2 The Live-Bearing Four-Footed Animals; the Birds • 5.3 The Egg-Laying Four-Footed Animals • 5.4 The Footless Animals • 5.5 The Fishes • 5.6 The Soft-Bodied Animals • 5.7 The Soft-Shelled Animals • 5.8 Mating Seasons: The Insects • 5.9 Mating Seasons: The Birds, Fishes, and Others • 5.10 Mating Seasons: The Fishes (1) • 5.11 Mating Seasons: The Fishes (2) • 5.12 Mating Seasons: The Soft-Bodied Animals and Hard-Shelled Animals • 5.13 Mating Seasons: The Birds • 5.14 The Ages of Mating • 5.15 The Hard-Shelled Animals • 5.16 The Sea Nettles and Sponges • 5.17 The Soft-Shelled Animals • 5.18 The Soft-Bodied Animals • 5.19 The Insects • 5.20 The Tracker Wasps • 5.21 The Bees (1) • 5.22 The Bees (2) • 5.23 The Hornet and the Wasp • 5.24 The *Bombukia* • 5.25 The Ants • 5.26 The Land Scorpions • 5.27 The Spiders • 5.28 The Crickets • 5.29 The Locusts • 5.30 The Cicadas • 5.31 The Fleas, Lice, and Other Parasites • 5.32 Mites and Other Small Animals • 5.33 The Turtle, the Lizard, and the Crocodile • 5.34 The Snakes

Book 6

6.1 The Birds • 6.2 The Egg • 6.3 The Egg of the Chicken • 6.4 The Pigeons • 6.5 The Vulture • 6.6 The Eagle • 6.7 The Cuckoo and the Hawk • 6.8 Brooding • 6.9 The Peafowl • 6.10 The Fishes and the Selachians (1) • 6.11 The Selachians (2) • 6.12 The Cetaceans and the Seal • 6.13 The Egg-Laying Fishes • 6.14 The Freshwater Fishes • 6.15 Spontaneous Generation among the Fishes • 6.16 The Eels • 6.17 When Offspring Come to Be • 6.18 The Live-Bearing Terrestrial Animals: Horses, Cows, and Pigs • 6.19 The Sheep and the Goats • 6.20 The Dogs • 6.21 The Cows • 6.22 The Horses • 6.23 The Asses • 6.24 The Mules • 6.25 The Ages of the Four-Footed Animals • 6.26 The Camel • 6.27 The Elephant • 6.28 The Wild Pigs • 6.29 The Deer • 6.30 The Bears • 6.31 The Lions • 6.32 The Hyenas • 6.33 The Hares • 6.34 The Foxes • 6.35 The Wolf, the Cat, and Others • 6.36 The Half-Asses • 6.37 The Mice

Book 7

7.1 Puberty in Human Beings • 7.2 The Menses • 7.3 Conception • 7.4 Pregnancy • 7.5 Fertility (1) • 7.6 Fertility (2); Resemblance between Parents and Offspring • 7.7 The Emission of Male Seed • 7.8 The Fetus and the Umbilical Cord • 7.9 Labor • 7.10 Cutting the Umbilical Cord • 7.11 Lactation • 7.12 Convulsions in Babies

Book 8

8.1 Animal Psychology • 8.2 Terrestrial and Aquatic Animals • 8.3 The Birds • 8.4 The Hard-Scaled Animals • 8.5 The Wild Sawtoothed Animals • 8.6 Modes of Drinking; The Pigs • 8.7 The Cows • 8.8 The Horses, Mules, and Asses • 8.9 The Elephants and Camels • 8.10 The Sheep and Goats • 8.11 The Insects • 8.12 Migration: Birds • 8.13 Going into Hiding: Fishes • 8.14 Going into Hiding: Insects • 8.15 Going into Hiding: Blooded Animals and Fishes • 8.16 Going into Hiding: Birds • 8.17 Going into Hiding: The Four-Footed Animals • 8.18 The Influence of Climate on the Birds • 8.19 The Influence of Climate on the Sea Fishes; Their Diseases • 8.20 Diseases of River and Lake Fishes; Influence of Climate • 8.21 Diseases of Pigs • 8.22 Diseases of Dogs • 8.23 Diseases of Cows • 8.24 Diseases of Horses • 8.25 Diseases of Asses • 8.26 Diseases of Elephants • 8.27 Diseases of Insects • 8.28 The Effects of Place on Animal Kinds • 8.29 The Effects Of Place on the Lives of the Animals • 8.30 The Effects of Pregnancy

Book 9

9.1 Animal Psychology; War among the Animals • 9.2 War and Friendship among the Sea Fishes • 9.3 The Goats and the Sheep • 9.4 The Cows and the Horses • 9.5 The Deer • 9.6 Practical Wisdom in Animals • 9.7 Practical Wisdom in Birds • 9.8 The Quails and the Partridges • 9.9 The Woodpeckers • 9.10 The Cranes and the Pelicans • 9.11 Bird Nests • 9.12 Aquatic Birds • 9.13 Other Birds • 9.14 The Halcyon • 9.15 The Hoopoe and Others • 9.16 Two Other Unidentified Birds • 9.17 Other Birds • 9.18 The Herons • 9.19 The Blackbirds • 9.20 The Thrushes • 9.21 The Bluebird • 9.22 The

Oriole and the *Malakokraneus* • 9.23 Other Birds • 9.24 The Jackdaws • 9.25 The Larks • 9.26 The Woodcock and the Starling • 9.27 The Ibises • 9.28 The Little Horned Owls • 9.29 The Cuckoo • 9.30 The Footless Birds • 9.31 The Ravens • 9.32 The Eagles • 9.33 A Scythian Bird • 9.34 Night Birds • 9.35 The *Kepphos* • 9.36 The Hawks • 9.37 The Marine Animals • 9.38 The Insects • 9.39 The Spiders • 9.40 The Bees • 9.41 The Wasps • 9.42 The Hornets • 9.43 The Bumblebees and the *Tenthrêdôn* • 9.44 The Lion and the *Thôs* • 9.45 The Bison • 9.46 The Elephant • 9.47 Avoidance of Incest in Camels and Horses • 9.48 The Dolphin • 9.49 Changes in Sexual Characteristics • 9.50 Castration and Rumination • 9.51 Changes in the Birds

Book 10 On Sterility

10.1 Causes of Sterility in Women (1) • 10.2 Causes of Sterility in Women (2) • 10.3 Causes of Sterility in Women (3) • 10.4 Causes of Sterility in Women (4) • 10.5 Causes of Sterility in Men • 10.6 Female Seed; Wind-Eggs • 10.7 Molar Pregnancies

On the Parts of Animals

C. D. C. Reeve 1177

Book 1

1.1 The Method of Inquiry of Natural Science (1) • 1.2 Dichotomous Division (1) • 1.3 Dichotomous Division (2) versus Correct Division (1) • 1.4 Correct Division (2) • 1.5 The Method of Inquiry of Natural Science (2)

Book 2

2.1 The Levels of Composition of Animals • 2.2 The Uniform Parts; the Hot and the Cold • 2.3 The Dry and the Wet; Blood • 2.4 Blood Fibers; Serum • 2.5 Fat and Suet • 2.6 Marrow • 2.7 The Brain • 2.8 Flesh • 2.9 Bone • 2.10 The Non-uniform Parts • 2.11 The Ears of the Four-Footed Animals • 2.12 Hearing in Various Animals • 2.13 Eyelids • 2.14 Eyelashes and Hair • 2.15 Eyebrows • 2.16 The Nose • 2.17 The Tongue

Book 3

3.1 The Teeth • 3.2 The Horns • 3.3 The Neck and Its Parts • 3.4 The Viscera • 3.5 The Blood Vessels • 3.6 The Lung • 3.7 The Liver and Spleen • 3.8 The Bladder • 3.9 The Kidneys • 3.10 The Diaphragm • 3.11 The Membrane of the Viscera • 3.12 Differences in the Viscera (1) • 3.13 Differences in the Viscera (2) • 3.14 The Stomach • 3.15 Rennet

Book 4

4.1 The Viscera of the Four-Footed Egg-Laying Animals and the Snakes • 4.2 The Gallbladder • 4.3 The Omentum • 4.4 The Mesentery • 4.5 The Bloodless Animals • 4.6 The External Parts of the Insects • 4.7 The External

Parts of the Hard-Shelled Animals • 4.8 The External Parts of the Soft-Shelled Animals • 4.9 The External Parts of the Bloodless Animals • 4.10 The Remaining External Parts of the Blooded Live-Bearing Animals • 4.11 The Egg-Laying Animals • 4.12 The Birds • 4.13 The Fishes • 4.14 The Libyan Ostrich

On the Movement of Animals

De Motu Animalium

Andrea Falcon 1279

1 The Internal Points of Rest • 2 The External Point of Rest • 3 Heavenly Movement • 4 A Closely Connected Puzzle • 5 Extending the Account to Qualitative and Quantitative Change • 6 The Moving Factors of the Animal • 7 How the Animal Moves • 8 Looking for the Internal Starting-Point of Animal Movement • 9 The Location of the Soul as the Internal Support of Animal Movement • 10 Innate Breath • 11 Involuntary and Non-voluntary Movements

On the Progression of Animals

De Incessu Animalium

Andrea Falcon 1293

1 What Is to Be Explained • 2 Explanatory Starting-Points • 3 External Supporting Point and Internal Complexity • 4 Dimensions • 5 Distribution of Feet and Cosmic Alignment • 6 The Centralized Progressive Movement System • 7 Points of Movement • 8 Number of Feet • 9 Bending • 10 Winged Animals • 11 Two-Footedness • 12 Leg Bending in Human Beings and Four-Footed Live-Bearing Animals • 13 Limb Bending • 14 Diagonal Leg Movement in Four-Footed Animals • 15 Leg Bending in Birds and Four-Footed Egg-Laying Animals • 16 Leg Bending in Bloodless Animals • 17 Leg Bending and Leg Movement in Crabs • 18 Animals That Live in Water • 19 Hard-Shelled Animals

On the Generation of Animals

C. D. C. Reeve 1313

Book 1

1.1 The Focus of the Treatise; Male and Female as Starting-Points • 1.2 The Sexes and Sexual Parts • 1.3 Testicles and Uterus in Different Animals • 1.4 Differences in the Spermatic Instruments in Males (1) • 1.5 Differences in the Spermatic Instruments in Males (2) • 1.6 Differences in the Spermatic

Instruments in Males (3) • 1.7 Differences in the Spermatic Instruments in Males (4) • 1.8 The Uterus; Live-Bearing and Egg-Laying Animals; Complete and Incomplete Eggs • 1.9 Internally and Externally Live-Bearing Animals • 1.10 Internally Egg-Laying and Externally Live-Bearing Animals • 1.11 More on the Uterus and Its Placement • 1.12 Placement of Uterus and Testicles • 1.13 Excretory and Spermatic Ducts in Females and Males • 1.14 Soft-Shelled Animal Copulation • 1.15 Soft-Bodied Animal Copulation • 1.16 Insect Copulation; "Spontaneous Generation" • 1.17 Do All Animals Emit Seed? Pangenesis • 1.18 Pangenesis Criticized; What Seed Is; Residues and Colliquescences • 1.19 Semen as a Residue of Nourishment and Blood; Menses as a Residue • 1.20 Menses as Impure Seed • 1.21 How Male Seed Is a Cause of What Comes to Be • 1.22 How the Male Contributes to Generation • 1.23 Plant Reproduction

Book 2

2.1 Sexual Dimorphism; Classification of Animals in Terms of Generation; Preformationism and Epigenesis • 2.2 The Nature of (Male) Seed • 2.3 Male Seed Contributes Movements Alone; the Inheritance of Nutritive and Perceptual Soul and Understanding; the Role of Breath; Active and Potential Possession of Soul • 2.4 Generation of the Human Beings and Other Complete Animals; Development and Nutrition of the Embryo (1) • 2.5 Why Female Needs Male • 2.6 Development of the Embryo (2) • 2.7 Nutrition of the Embryo (2); Hybrids and Sterility • 2.8 Mules

Book 3

3.1 The Birds (1): Wind-Eggs; the White and the Yellow • 3.2 The Birds (2): Shape of Eggs; Growth of Eggs; Brooding; Umbilical Cords • 3.3 The Fishes (1): The Selachians • 3.4 The Fishes (2): Non-selachians • 3.5 The Fishes (3): Erroneous Theories of Mating • 3.6 Erroneous Theories of Bird Mating; the Trochus and Hyena • 3.7 Mating of Fishes; Wind-Eggs in the Birds • 3.8 The Soft-Bodied and Soft-Shelled Animals • 3.9 The Insects • 3.10 The Bees • 3.11 The Hard-Shelled Animals

Book 4

4.1 Causes of Sex Differentiation in the Embryo • 4.2 Evidence for the Proposed Theory of Sex Differentiation in the Embryo • 4.3 Heredity; Monstrosities (1) • 4.4 Monstrosities (2) • 4.5 Superfetation • 4.6 Degrees of Completeness in Neonates • 4.7 Molar Pregnancies • 4.8 Milk • 4.9 Why Animals Are Born Head First • 4.10 Periods of Pregnancy

Book 5

5.1 Affections of Animals and Their Parts; Sleep; Color of Eyes; Sharpness of Sight • 5.2 Sharpness of Smell and Hearing • 5.3 Hair (1) • 5.4 Hair (2) • 5.5 Hair (3) • 5.6 Color of Animals • 5.7 Voices of Animals • 5.8 Teeth of Animals

— VOLUME 2 —

METAPHYSICS

C. D. C. Reeve 1

Book 1 (Alpha)

1.1 Theoretical Wisdom as a Science Concerned with Primary Causes and Starting-Points • 1.2 Theoretical Wisdom as the Science of God • 1.3 Earlier Philosophers Recognized the Material Cause • 1.4 The Discovery of the Efficient Cause • 1.5 Pythagoreans and Eleatics: Intimations of the Formal Cause • 1.6 Material and Formal Causes in Plato • 1.7 Prior Thinkers and the Four Causes • 1.8 Criticism of Pre-Platonic Philosophers • 1.9 Criticism of the Theory of Forms • 1.10 Earlier Philosophy Reveals No Causes beyond the Four

Book 2 (Little Alpha)

2.1 The Primary Causes of the Beings and Our Understanding of them • 2.2 There Must Be Some Starting-Point or Primary Cause of the Beings • 2.3 Diverse Modes of Argument

Book 3 (Beta)

3.1 Puzzles (P1–14) about Primary Starting-Points and Causes • 3.2 Discussion of P1–5 • 3.3 Discussion of P6–7 • 3.4 Discussion of P8–11 • 3.5 Discussion of P14 • 3.6 Discussion of P12, P13, P14a

Book 4 (Gamma)

4.1 The Science of Being qua Being versus the Special Sciences • 4.2 The Many Ways in Which Something Is Said to Be • 4.3 Axioms and the Principle of Non-contradiction • 4.4 Seven Arguments (A1–7) for the Principle of Non-contradiction • 4.5 Discussion of Protagoras' Argument That Man Is the Measure of All Things • 4.6 Discussion Continued • 4.7 The Principle of Excluded Middle • 4.8 Nothing Is True and Everything Is True

Book 5 (Delta)

5.1 Starting-Point • 5.2 Cause • 5.3 Element • 5.4 Nature • 5.5 Necessary • 5.6 One • 5.7 Be • 5.8 Substance • 5.9 Same • 5.10 Opposites • 5.11 Prior and Posterior • 5.12 Capacity, Potentiality, Power • 5.13 Quantity • 5.14 Quality • 5.15 Relative • 5.16 Complete • 5.17 Limit • 5.18 In Virtue of Which • 5.19 Disposition • 5.20 Having (or State) • 5.21 Affection • 5.22 Privation (Lack) • 5.23 Have (Hold) • 5.24 Of (From) • 5.25 Part • 5.26 Whole • 5.27 Docked • 5.28 Kind (Race) • 5.29 False • 5.30 Coincident

Book 6 (Epsilon)

6.1 The Three Theoretical Philosophies • 6.2 Coincidental Being and What Happens for the Most Part • 6.3 Starting-Points of What Happens by Luck • 6.4 Being True and Being False

Book 7 (Zeta)

7.1 Substance as Primary Being • 7.2 Are There Any Substances beyond Perceptible Ones? • 7.3 Sketch of Substance • 7.4 Logico-Linguistic Investigation of Essence and Definition • 7.5 Definition Continued • 7.6 Is Each Thing the Same as Its Essence? • 7.7 Form in Matter-Form Compounds (1) • 7.8 Form in Matter-Form Compounds (2) • 7.9 Form in Matter-Form Compounds (3) • 7.10 Definition's Relation to Form • 7.11 Form and Its Parts • 7.12 Definition Again • 7.13 Are Universals Substances? • 7.14 Are Platonic Forms Separable Substances? • 7.15 No Definitions or Demonstrations of What Is Particular • 7.16 Most Things That Seem to Be Substances Are in Fact Capacities • 7.17 Substance as Starting-Point and Cause

Book 8 (Eta)

8.1 Summary of Book 7 • 8.2 Substance as Activation of Perceptibles • 8.3 Composite Substances versus Their Activations • 8.4 The Matter of Composite Substances • 8.5 How the Matter of a Thing Is Related to Its Contrary States • 8.6 What Makes a Definiens or a Definiendum One

Book 9 (Theta)

9.1 Potential Being (Capacities) • 9.2 Rational and Non-rational Capacities • 9.3 The Megarians on Capacities • 9.4 Capacities and Incapacities • 9.5 Capacities and Their Acquisition; Rational Capacities • 9.6 Being as an Activity; What an Activity Is • 9.7 When a Thing Is Potentially Something • 9.8 The Priority of Activity to Potentiality • 9.9 Activity More Estimable Than Potentiality; Activity and Potentiality in Knowledge • 9.10 True and False Being; the Case of Incomposites; Understanding and Error

Book 10 (Iota)

10.1 The Ways in Which Beings Are Said to Be Intrinsically One; the Being for a One • 10.2 The Substance and Nature of the One • 10.3 Same, Similar, Distinct, Different, Contrary • 10.4 Contrariety • 10.5 Puzzles about How the Equal Is Opposed to the Great and the Small • 10.6 Puzzles about How the One Is Opposed to the Many • 10.7 Contraries and Intermediates • 10.8 Distinctness in Form • 10.9 The Case of Female and Male • 10.10 Things Capable and Things Incapable of Passing Away Must Be Distinct in Kind

Book 11 (Kappa)

11.1 Puzzles from 3.1 Revisited ($P_{1\text{-}8}$) • 11.2 More Puzzles from 3.1 Revisited ($P_{9\text{-}16}$) • 11.3 4.1–2 Revisited • 11.4 Parts of 4.3 Revisited • 11.5 Parts of 4.3 Revisited • 11.6 Parts of 4.4–5 Revisited • 11.7 6.1 Revisited • 11.8 6.2–4

Revisited • 11.9 Parts of *Physics* 3 Recapitulated: Movement • 11.10 More Parts of *Physics* 3 Recapitulated: The Unlimited • 11.11 Parts of *Physics* 5 Recapitulated • 11.12 More Parts of *Physics* 5 Recapitulated

Book 12 (Lambda)

12.1 Substance and Its Varieties • 12.2 Matter and Change • 12.3 Coming to Be and Its Causes • 12.4 The Causes and Starting-Points of Distinct Substances Are in a Way the Same • 12.5 More on the Causes and Starting-Points of Substances • 12.6 The Need for an Eternal Immovable Substance That Is in Essence an Activity • 12.7 The Primary God as Immovable Mover • 12.8 The Number of Immovable Movers and Why There Is Only One Heaven • 12.9 Divine Understanding and the Primary God • 12.10 The Primary God and the Nature of the Whole

Book 13 (Mu)

13.1 Mathematical Objects and Platonic Forms as Substances and Causes • 13.2 The Ways Objects of Mathematics Do Not Exist • 13.3 The Way Objects of Mathematics Do Exist • 13.4 The Socratic Origins of the Theory of Forms; 1.6–9 Partly Recapitulated • 13.5 What the Forms Contribute to Perceptibles: 1.9 Partly Recapitulated • 13.6 Numbers as Separable Substances: Pythagoreans and Platonists • 13.7 Plato on Units • 13.8 Speusippus, Xenocrates, the Pythagoreans: Numbers as Separable Intrinsic Beings (1) • 13.9 Numbers as Separable Intrinsic Beings (2); Forms as Universals and Particulars • 13.10 The Separability of Elements and Starting-Points; the Scientific Knowability of Substances

Book 14 (Nu)

14.1 Contraries Cannot Be Starting-Points • 14.2 Eternal Things as Consisting of Elements; the One Plus Something Else as Elements; How Not Being Can Come from Being and Be Many • 14.3 The Existence of Numbers and Mathematical Objects • 14.4 The Relation of Mathematical Elements and Starting-Points to the Good and the Noble • 14.5 How the Beings Come from Numbers and Other Related Puzzles • 14.6 More on Numbers and the Good: Ratios

NICOMACHEAN ETHICS

C. D. C. Reeve 233

Book 1

1.1 Goods and Ends • 1.2 Ethics Is a Sort of Politics • 1.3 Exactness in Ethics • 1.4 Views about Happiness • 1.5 Three Sorts of Lives • 1.6 Plato on the Good • 1.7 Completeness, Self-Sufficiency, and Human Work • 1.8 The Argument Defended • 1.9 How Happiness Is Achieved • 1.10 When to Count a Human Being Happy • 1.11 Death and Happiness • 1.12 Is Happiness Praiseworthy or Estimable? • 1.13 The Soul and Its Virtues

Book 2

2.1 The Importance of Habit • 2.2 Ethics Is a Practical Science • 2.3 Pleasure and Pain • 2.4 Action and Character • 2.5 Virtue of Character Defined (1) • 2.6 Virtue of Character Defined (2) • 2.7 Individual Virtues of Character • 2.8 Means and Extremes • 2.9 Achieving the Mean

Book 3

3.1 Voluntary and Involuntary Action • 3.2 Deliberate Choice • 3.3 Deliberation • 3.4 Wish • 3.5 Character and End • 3.6 Courage (1) • 3.7 Courage (2) • 3.8 Courage-Like Conditions • 3.9 Courage, Pleasure, and Pain • 3.10 Temperance (1) • 3.11 Temperance (2) • 3.12 Intemperance

Book 4

4.1 Generosity • 4.2 Magnificence • 4.3 Greatness of Soul • 4.4 Nameless Virtue Concerned with Honor • 4.5 Mild-Manneredness • 4.6 Being Ingratiating and Being Disagreeable • 4.7 Truthfulness • 4.8 Wit • 4.9 Shame

Book 5

5.1 Sorts of Justice • 5.2 Special and General Justice • 5.3 Distributive Justice • 5.4 Rectificatory Justice • 5.5 Justice in Exchange • 5.6 Political Justice • 5.7 Natural Justice and Legal Justice • 5.8 Voluntary and Involuntary Justice and Injustice • 5.9 Puzzles about Doing and Suffering Unjust Actions • 5.10 Decency • 5.11 Doing Injustice to Oneself

Book 6

6.1 Correct Reason and the Virtues of Thought • 6.2 Action, Truth, and Deliberate Choice • 6.3 Scientific Knowledge • 6.4 Craft Knowledge • 6.5 Practical Wisdom • 6.6 Understanding • 6.7 Theoretical Wisdom and Practical Wisdom • 6.8 Practical Wisdom and Politics • 6.9 Good Deliberation • 6.10 Comprehension • 6.11 Consideration, Understanding, and Practical Wisdom • 6.12 Practical Wisdom, Theoretical Wisdom, and Cleverness • 6.13 Natural Virtue, Virtue in the Strict Sense, and Practical Wisdom

Book 7

7.1 Beastliness, Lack of Self-Control, Method • 7.2 Puzzles about Lack of Self-Control • 7.3 Lack of Self-Control and Knowledge • 7.4 Unconditional Lack of Self-Control • 7.5 Beast-Like, Diseased, and Morbid Conditions • 7.6 Lack of Self-Control Due to Spirit and Appetite • 7.7 Lack of Self-Control, Intemperance, Softness, and Resilience • 7.8 Why Intemperance Is Worse Than Lack of Self-Control • 7.9 Self-Control • 7.10 Lack of Self-Control and Practical Wisdom • 7.11 Pleasure and Pain • 7.12 Pleasure and Goodness • 7.13 Pleasure and Happiness • 7.14 Bodily Pleasures

Book 8

8.1 Views about Friendship • 8.2 The Objects of Love and Friendship • 8.3 Three Forms of Friendship • 8.4 Comparisons between the Forms of Friendship (1) • 8.5 Friendship as Activity and as State • 8.6 Comparisons between the Forms of Friendship (2) • 8.7 Friendships between Unequals • 8.8 Comparisons between the Forms of Friendship (3) • 8.9 Friendships in Different Communities • 8.10 Constitutions • 8.11 Friendships in Different Constitutions • 8.12 Friendships in Families • 8.13 Complaints in Friendships in Accord with Equality • 8.14 Complaints in Friendships in Accord with Inequality

Book 9

9.1 Resolving Disputes That Arise in Friendship • 9.2 Puzzles about the Demands of Different Friendships • 9.3 Puzzles about Dissolving Friendships • 9.4 Friendship and Self-Love • 9.5 Friendship and Goodwill • 9.6 Friendship and Concord • 9.7 Benefactors and Beneficiaries in Friendships • 9.8 Puzzles about Self-Love • 9.9 Does a Happy Person Need Friends? • 9.10 How Many Friends Should We Have? • 9.11 Friends in Good Luck and in Bad • 9.12 Living Together

Book 10

10.1 How to Discuss Pleasure • 10.2 Disputes about Pleasure • 10.3 Pleasure Is a Good, Not the Good • 10.4 Pleasure as Unimpeded Activity • 10.5 Different Forms of Pleasure • 10.6 Happiness Reconsidered • 10.7 Happiness as Contemplation • 10.8 Two Sorts of Happiness • 10.9 Politics, Legislators, and Happiness

†Magna Moralia

The Great Ethics

C. D. C. Reeve 407

Book 1

1.1 Ethics, Virtue, and the Good • 1.2 Divisions of Goods • 1.3 Happiness • 1.4 Happiness and Virtue • 1.5 Parts of the Soul and Their Virtues; How the Virtues of Character Are Destroyed • 1.6 Pain, Pleasure, and Habituation • 1.7 Feelings, Capacities, and States; the Mean • 1.8 More on Feelings and the Mean • 1.9 Excess, Deficiency, and the Mean • 1.10 Starting-Points • 1.11 Starting-Points of Voluntary Action • 1.12 The Voluntariness of Actions Due to Appetite • 1.13 The Voluntariness of Actions Due to Appetite, to Spirit, and to Wish • 1.14 Force and Compulsion (1) • 1.15 Force and Compulsion (2) • 1.16 The Voluntary Is What Proceeds from Thought • 1.17 Deliberate Choice • 1.18 Ends and What Furthers Them • 1.19 Virtue's End Is the Noble • 1.20 Courage • 1.21 Temperance • 1.22 Mild-Manneredness • 1.23 Generosity • 1.24 Generosity and Ungenerosity • 1.25 Greatness of

Soul • 1.26 Magnificence • 1.27 Indignation • 1.28 Dignity • 1.29 Shame • 1.30 Wit • 1.31 Friendliness • 1.32 Truthfulness • 1.33 Justice • 1.34 The Virtues of Thought

Book 2

2.1 Decency • 2.2 Consideration • 2.3 Good Deliberation; Puzzles about Justice and Practical Wisdom • 2.4 Self-Control and Lack of Self-Control • 2.5 Beastliness • 2.6 Puzzles Concerning Self-Control and Lack of Self-Control • 2.7 Pleasure • 2.8 Good Luck • 2.9 Noble-Goodness • 2.10 Correct Reason • 2.11 Friendship • 2.12 Paternal Friendship • 2.13 Self-Love • 2.14 Will the Excellent Person Love Himself Most? • 2.15 Self-Sufficiency • 2.16 How Many Friends Should One Have? • 2.17 How Friends Should Be Treated

EUDEMIAN ETHICS

C. D. C. Reeve 477

Book 1

1.1 What Happiness Consists In and How It Is to Be Acquired • 1.2 Happiness and Its Preconditions • 1.3 Beliefs about Happiness • 1.4 Three Lives • 1.5 Which Things in Life Are Choiceworthy • 1.6 The Method of Inquiry • 1.7 The Greatest of Human Goods • 1.8 What the Best Good Is

Book 2

2.1 Virtue of Character and of Thought; the Work of the Human Soul; Happiness • 2.2 Character, Feeling, Capacity, and State • 2.3 Virtue as a Mean (1) • 2.4 Virtue, Pleasure, and Pain • 2.5 Virtue as a Mean (2) • 2.6 Human Beings as Starting-Points of Action • 2.7 Voluntary and Involuntary (1) • 2.8 Voluntariness, Deliberate Choice, Force, and Compulsion • 2.9 Voluntary and Involuntary (2) • 2.10 Deliberate Choice • 2.11 Virtues, Ends, and What Furthers Ends

Book 3

3.1 Courage • 3.2 Temperance and Intemperance • 3.3 Mild-Manneredness and Harshness • 3.4 Generosity • 3.5 Greatness of Soul • 3.6 Magnificence • 3.7 Other Good and Bad States of Character

Books 4–6 = *Nicomachean Ethics* Books 5–7

Book 7

7.1 Friendship • 7.2 Nature and the Kinds of Friendship • 7.3 Friendship and Equality • 7.4 Friendship between Unequals • 7.5 Friendship and Likeness • 7.6 Self-Friendship (Self-Love) • 7.7 Friendship, Concord, and Goodwill • 7.8 Benefactors and Beneficiaries • 7.9 Friendships and Communities • 7.10 Political Friendship • 7.11 Problems about Friendship • 7.12 Friendship and Self-Sufficiency

Book 8

8.1 Are Virtues Sciences? 8.2 Luck and Happiness • 8.3 Noble-Goodness, Complete Virtue, and Correct Reason

Politics

C. D. C. Reeve 553

Book 1

1.1 The City and Its Rule • 1.2 The Emergence and Naturalness of the City • 1.3 The City's Parts: Household, Master, and Slave • 1.4 The Nature of the Slave • 1.5 Natural Slaves (1) • 1.6 Natural Slaves (2) • 1.7 Mastership and Slavecraft • 1.8 Property Acquisition and Household Management • 1.9 Wealth Acquisition and the Nature of Wealth • 1.10 Wealth Acquisition, Household Management, Usury • 1.11 Practical Aspects of Wealth Acquisition; Monopolies • 1.12 The Rule of Women and Children • 1.13 The Virtues of Men, Women, Children, and Slaves

Book 2

2.1 Constitutions Proposed by Others • 2.2 The Constitution of the *Republic*: Unity • 2.3 The Constitution of the *Republic*: Women and Children (1) • 2.4 The Constitution of the *Republic*: Women and Children (2) • 2.5 The Constitution of the *Republic*: Property • 2.6 The Constitution of the *Laws* • 2.7 The Constitution of Phaleas of Chalcedon • 2.8 The Constitution of Hippodamus of Miletus • 2.9 The Spartan Constitution • 2.10 The Cretan Constitution • 2.11 The Carthaginian Constitution • 2.12 The Constitution of Solon and Other Legislators

Book 3

3.1 City and Citizen • 3.2 Pragmatic Definitions of the Citizen • 3.3 The Identity of a City • 3.4 Virtues of Man and Citizen, Rulers and Ruled • 3.5 Should Craftsmen Be Citizens? • 3.6 Correct and Deviant Constitutions • 3.7 The Classification of Constitutions • 3.8 Defining Oligarchy and Democracy • 3.9 Justice and the End of the City • 3.10 Control of the City • 3.11 Majority Control? • 3.12 Justice, Equality, and Control • 3.13 The Just Basis for Control • 3.14 Kinds of Kingship • 3.15 Kingship and Law • 3.16 Absolute Kingship • 3.17 Constitutions Suited to Different Peoples • 3.18 The Best Constitution

Book 4

4.1 The Science of Politics • 4.2 Deviant Constitutions and the Tasks of Book 4 • 4.3 Why There Are Several Constitutions • 4.4 Democracy and Oligarchy • 4.5 Forms of Oligarchy • 4.6 Forms of Democracy and Oligarchy • 4.7 Forms of Aristocracy • 4.8 Polity (1) • 4.9 Polity (2) • 4.10 Forms of Tyranny

• 4.11 The Middle Class (1) • 4.12 The Middle Class (2) • 4.13 Subtle Devices Used in Constitutions • 4.14 The Deliberative Element in a Constitution • 4.15 Offices • 4.16 The Judicial Element

Book 5

5.1 Changing and Preserving Constitutions • 5.2 Principal Starting-Points of Political Change • 5.3 Particular Starting-Points of Political Change (1) • 5.4 Particular Starting-Points of Political Change (2) • 5.5 Political Change in Democracies • 5.6 Political Change in Oligarchies • 5.7 Political Change in Aristocracies • 5.8 How to Preserve Constitutions (1) • 5.9 How to Preserve Constitutions (2) • 5.10 Changing and Preserving Monarchies • 5.11 Preserving Kingships and Tyrannies • 5.12 Long-Lasting Tyrannies; Plato on Political Change

Book 6

6.1 Mixed Constitutions and Forms of Democracy • 6.2 The Hypothesis of Democracy • 6.3 Democratic Equality • 6.4 Ranking Democracies • 6.5 Preserving Democracies • 6.6 Preserving Oligarchies (1) • 6.7 Preserving Oligarchies (2) • 6.8 Sorts of Office

Book 7

7.1 The Most Choiceworthy Life • 7.2 The Political Life and the Philosophical Life (1) • 7.3 The Political Life and the Philosophical Life (2) • 7.4 The Size of the Best City • 7.5 Territory • 7.6 Access to the Sea and Naval Power • 7.7 The Influences of Climate • 7.8 Necessary Parts of the City • 7.9 Offices and Who Should Hold Them • 7.10 The Division of the Territory • 7.11 Location and Fortifications • 7.12 Markets, Temples, and Communal Messes • 7.13 Happiness and Virtue • 7.14 Rulers and Ruled: Their Education • 7.15 Education and Leisure • 7.16 Regulation of Marriage and Procreation • 7.17 Education of Children

Book 8

8.1 Education Should Be Communal • 8.2 The Aims of Education • 8.3 Education and Leisure; Music (1) • 8.4 Athletic Training • 8.5 Music (2) • 8.6 Music (3) • 8.7 Music (4)

RHETORIC

C. D. C. Reeve 739

Book 1

1.1 What Rhetoric Is • 1.2 Means of Persuasion; Likelihoods, Signs, and Proofs; Common and Special Topics • 1.3 The Three Kinds of Rhetoric • 1.4 Deliberative Oratory (1) • 1.5 Deliberative Oratory (2) • 1.6 Deliberative Oratory (3) • 1.7 Deliberative Oratory (4) • 1.8 Deliberative Oratory (5)

• 1.9 Epideictic Oratory • 1.10 Judicial Oratory (1) • 1.11 Judicial Oratory (2) • 1.12 Judicial Oratory (3) • 1.13 Judicial Oratory (4) • 1.14 Judicial Oratory (5) • 1.15 Judicial Oratory (6)

Book 2

2.1 Rhetoric Is for the Sake of Judgment • 2.2 Anger • 2.3 Mild-Manneredness • 2.4 Friendliness and Enmity • 2.5 Fear and Confidence • 2.6 Shame and Shamelessness • 2.7 Gratitude and Ingratitude • 2.8 Pity • 2.9 Indignation • 2.10 Envy • 2.11 Jealousy • 2.12 The Character of Young People • 2.13 The Character of Old People • 2.14 The Character of Those in Their Prime • 2.15 Good Breeding • 2.16 Wealth • 2.17 Capacity • 2.18 Notions Common to All Kinds of Speeches • 2.19 Possible and Impossible; the Past; the Future; Amplifying and Diminishing • 2.20 Means of Persuasion Common to All Kinds of Speeches • 2.21 Maxims • 2.22 Enthymemes • 2.23 Topics for Enthymemes • 2.24 Topics for Apparent Enthymemes • 2.25 Refutation • 2.26 Amplifying and Diminishing; Refutative Enthymemes

Book 3

3.1 Style and Delivery • 3.2 Virtue of Style • 3.3 Frozen Effects and Inappropriate Metaphors • 3.4 Similes and Metaphors • 3.5 The Constituents of Good Greek Style • 3.6 The Weight of a Style • 3.7 Appropriateness • 3.8 The Scheme or Rhythm of a Style • 3.9 Continuous versus Compact Style • 3.10 The Sources of Elegant and Popular Expressions • 3.11 Setting Things before the Eyes • 3.12 Each Kind of Rhetoric Has Its Own Style • 3.13 Arrangement • 3.14 The Introduction • 3.15 Topics Concerning Accusation • 3.16 Narration • 3.17 Means of Persuasion • 3.18 Questioning • 3.19 Epilog

Poetics

PREFACE

These two volumes aim to provide the Anglophone reader with accurate and consistent translations of authoritative editions of the complete works of Aristotle, together with one (slightly) dubious work, the *Magna Moralia*, and one work not by Aristotle, but from his school, the *Athenian Constitution*. The former, whatever its exact provenance, is a sufficiently important source for readers interested in understanding Aristotle's ethical thinking to be included with the *Nicomachean Ethics* and *Eudemian Ethics*. The latter merits inclusion as the one surviving example of the sort of empirical constitutional history on which Aristotle's political theorizing is in part based.

Other works traditionally associated with Aristotle, though probably not by him, are in most cases included in Immanuel Bekker's standard edition (Berlin, 1831)—these, along with some others not included in Bekker, will be collected in a separate volume. Citations are made to this edition, in the canonical form of abbreviated title, page number and column letter (a, b), or occasionally just by book and chapter numbers. Line numbers, which are to the editions specified, are approximate in the translations, where they appear in the margins at the end of the lines to which they refer, or within upright lines in the epub edition.

Though the present organization better serves readers interested primarily in Aristotle himself than one modeled on Bekker, it results in gaps in the order of the Bekker page numbers. The Introduction indicates where these occur and discusses how what we call the "*Complete Works*" of Aristotle came about.

Accuracy is, of course, difficult to achieve with works that are so diverse in subject matter and so complex, and we are grateful to the many experts who have helped the translators achieve it. We are grateful to the translators themselves for agreeing to translate (especially) key terms in a consistent way, so that readers can move somewhat seamlessly from one treatise to another, confident that what is, for example, *epistêmê* ("scientific knowledge"), *ousia* ("substance"), *to ti ên einai* ("essence"), or *nous* ("understanding") in one treatise is not called something else in another. These terms, along with many others, are included in the extensive Annotated Glossary of Terms, with which readers—especially those unfamiliar with Aristotle—should acquaint themselves before venturing too far into the works themselves. The longer, more interpretative entries, however, express the views of their author and are a place to start, not to finish—a first step in coming to understand Aristotle for oneself. The Introduction also discusses some of the same material as part of a connected narrative describing Aristotle's philosophy as a whole. The numerous people and places Aristotle mentions are briefly identified in the annotated index of these.

A number of the translations first appeared, with extensive introductions and notes, in the New Hackett Aristotle series. Though these have been substantially revised and corrected, they can be usefully consulted by readers in search of further guidance. The

sparser notes included here direct the reader to illuminating passages and help make particularly difficult ones intelligible.

In general, the translations are traditional where the costs of innovation exceed the benefits, innovative where the benefits exceed the costs. In the case of *phronêsis*, *aretê*, and *eudaimonia*, for example, the traditional and largely entrenched translations—"practical wisdom," "virtue," and "happiness"—have been preserved for these reasons, while those of *eidos* as "form," "kind," or "species," *genos* as "kind" or "genus," *diaphora* as "difference" or "differentia," and *ergon* as "function," or "work," which are retained in many of the Hackett series editions, have been abandoned systematically in favor of "form," "kind," "difference," and "work" alone. Readers can now generally determine for themselves how a given occurrence of any of these terms is best understood.

Aristotle's treatises are, in some cases, more commonly known by their Latin titles, in others, by their English ones. We have generally followed standard practice in this regard, especially in the case of abbreviated titles, since this makes it easier to correlate the texts with commentaries and other secondary materials. Some titles, however rendered, nonetheless require comment. This has been supplied in the pertinent headnotes and in the Introduction.

The editions of the Greek texts themselves record in the textual apparatus at the bottom of the page various manuscript readings alternative to the ones printed in the body of the text. In some cases, translators have preferred one of these readings and have, when important, indicated so in the notes. These, which alone include non-transliterated Greek, will be of interest to readers who are also consulting the Greek text and can be ignored by others. Occasional material in square brackets in the text, as well as the various chapter headings and figures, have been added by the translators, typically for intelligibility.

Editorial responsibilities were divided as follows: C. D. C. Reeve established the norms of translation and edited the translations not credited to him, ensuring—among other things—that they follow these norms. Pavlos Kontos was responsible for the final editing of all the translations and for ensuring their accuracy and correctness. Everything else was their joint responsibility.

INTRODUCTION*

Christof Rapp

1. Who Was Aristotle?

Aristotle was a Greek philosopher who lived in the fourth century BC. He is widely regarded as one of the greatest figures in Western philosophy. Born in 384 in the city of Stagira in northern Greece, he joined Plato's Academy in Athens when he was about seventeen years old, where he then studied and taught for nearly two decades. Around the time of Plato's death in 347, Aristotle left Athens and traveled to the city of Assos in Asia Minor. He later moved to the nearby island of Lesbos. In 342 he received an invitation from King Philip II of Macedon to tutor his son Alexander, who would later become known as Alexander the Great. Aristotle returned to Athens in 335 and established his own school, the Lyceum. This school came to be known as the Peripatos, and its members as Peripatetics. Due to rising anti-Macedonian sentiment in Athens in 323, Aristotle withdrew to Chalcis on the island of Euboea, where he passed away in 322. Accordingly, it is common to distinguish between Aristotle's first stay in Athens (approximately between 367/366 and 348/347), his "exile" on Lesbos and in northeastern Greece (approximately between 348/347 and 335), and his second stay in Athens (until 323/322).

The city of Stagira, where Aristotle was born and where he spent parts of his childhood, is located on the peninsula of Chalcidice in the Macedonian part of modern Greece. However, it was not part of the ancient Macedonian Empire at the time Aristotle lived there. When the Macedonians attacked the city of Olynthus, an ally of Athens, in 349, they also destroyed Aristotle's hometown of Stagira. Still, in the Athens of those days, Aristotle might have been perceived as a friend of the Macedonians, probably due to his family's ties to the Macedonian royal court. His parents, Nicomachus and Phaestis, both came from families with a medical background, and his father was reported to be doctor to King Amyntas III of Macedon, the father of Philip II. It might be owing to the same familial connection that Aristotle was commissioned to be the tutor of young Alexander. During his time in Asia Minor Aristotle married a woman by the name of Pythias; probably from this marriage resulted his daughter, also named Pythias, and his son, named after Aristotle's father, Nicomachus. After Pythias' death, Herpyllis (who is also mentioned in Aristotle's last will) became his partner. During his exile from Athens

* For the thorough revision of my text I am grateful to the editors; for the content of section 2, I am indebted to my long-standing collaboration with Oliver Primavesi.

he also met the person who became his closest student and friend, Theophrastus. Based on the flora and fauna of the island of Lesbos, it can be shown that it was there that Aristotle and Theophrastus commenced their zoological and botanical studies.

While Aristotle's philosophy is clearly and significantly influenced by Plato, he diverges from his mentor in numerous important ways. One of his primary innovations is the division of philosophical inquiry into several distinct and independent subjects, including logic, zoology, biology, cosmology, ethics, and political theory. He counters Plato's hypothesis concerning the existence of eternal, separate Forms. Nevertheless, form remains a central concept in his own philosophy. Unlike Plato's Forms, Aristotle's forms do not exist independently from the perceptible world, but instead generally inform a portion of matter, with form and matter collectively constituting specific entities in the perceptible world, such as particular animals or plants.

Even though Plato's influence is significant, Aristotle's own thought was shaped not only by Plato and the philosophers of the Platonic Academy, but also by a wide array of other thinkers, crafts, and sciences. Notably, Aristotle is renowned for his thorough discussions of the Presocratic philosophers, thinkers who lived between the sixth century BC and the time of Socrates' death in 399. For instance, he extensively examines Eleatic philosophers such as Parmenides and Zeno of Elea, Heraclitus, the Pythagoreans, Anaxagoras, Empedocles, and Democritus. In fact in some cases, Aristotle's reports and discussions serve as the most reliable sources for these thinkers' theses and theories. In his work on cosmology and primary philosophy (metaphysics), Aristotle often draws on the expertise of the celebrated astronomers of his time.

He also displayed a keen interest in contemporary mechanical studies, occasionally appealing to mechanical laws and referencing various mechanical devices. His biological works reveal a substantial understanding of the contemporary craft of medicine and incorporate knowledge from sources such as hunters, fishermen, animal breeders, beekeepers, and travel reports. Within his school, the Lyceum, individual students worked on the history of musicology and medicine. Aristotle organized the compilation of a collection of 158 political constitutions from past and present (see Diogenes Laertius 5.27). He is also cited as the author of a collection of rhetorical manuals (F97–98). In a similar vein, his *Poetics* proves his intimate familiarity with Greek epic and tragedy.

Taking all these endeavors within his widely ramified oeuvre into account, one gains the impression that Aristotle utilized his lifespan to thoroughly explore nearly all available fields of knowledge, science, and culture at the time and that he was open to influences of all kinds. In some fields, he offered truly original and groundbreaking insights (for example, on logic or zoology), while in others he reorganized existing crafts and sciences, and in some cases managed to leave them in a better structured state.

2. The *Complete Works* of Aristotle: What Is Included and How the Collection Came About

What is included in an edition called the "*Complete Works*" of Aristotle? Everything Aristotle ever wrote? Or everything he ever published? Unfortunately, the formation of the Aristotelian oeuvre is more complicated and, also, much more fortuitous than these two possible answers may suggest. For, as a matter of fact, a significant part of what Aristotle wrote or published is lost (probably for all time), whereas major parts of what we nowadays regard as the essential works of Aristotle—for example, his *Metaphysics*, *Prior Analytics*, or *Nicomachean Ethics*—were probably never meant for publication. But let us take one thing at a time!

What we now regard as "the works" or "the complete works" of Aristotle ultimately originates from an ancient collection of treatises attributed to him. This collection was originally compiled between the first century BC and the second century AD, a few centuries after Aristotle's death. These works have been transmitted under the name of "Aristotle" and are commonly known as the *Corpus Aristotelicum*. For centuries, the works included in it were copied and transmitted as manuscripts, because they were considered the authentic contributions of the renowned Greek philosopher Aristotle, representing his complete or essential body of work.

None of the works within the *Corpus* have survived as ancient papyri. The oldest existing Greek manuscripts of them date back to the ninth century AD. During this period, ancient majuscule manuscripts (lacking accents and spaces) of esteemed authors were transliterated in Constantinople into more readable minuscule manuscripts, featuring accentuation and spacing between words. Around the same time, starting in the ninth century, a well-orchestrated initiative in Baghdad aimed to translate Aristotle's works into Arabic, sometimes using Syriac translations, as certain key translators were Syriac scholars proficient in both Greek and Arabic. The first printed edition of the Greek text containing all the works in the *Corpus Aristotelicum* (except for the *Poetics* and the *Rhetoric*), known as the *Aldina*, was published in Venice between 1495 and 1498 by the editor Aldus Manutius.

The basis for modern scholarship on Aristotle's works is the critical edition organized by the Prussian Academy of Sciences in Berlin and edited by Immanuel Bekker in 1831. This edition, consisting of two volumes, slightly reorganized the order of the treatises relative to the *Aldina* and resulted from a comparison of the greater number of manuscripts available at that time. However, it retained the same treatises already present in the *Aldina* (including the *Poetics* and the *Rhetoric*), all of which were attributed to the *Corpus Aristotelicum*. The importance of the Bekker edition is reflected in the fact that Aristotle scholars continue to reference its pagination when quoting Aristotle's works. While there is no recent complete edition of Aristotle's Greek texts that has replaced the Bekker edition, various recent editions of specific works offer Greek texts based on the

examination of more manuscripts and an improved understanding of the interdependence between different manuscript families.

The modern reader's comprehension of what qualifies as a genuinely Aristotelian work is thus still fundamentally influenced by the *Corpus Aristotelicum*. In general, it serves as a solid guide for what should be encompassed in a complete works. Nevertheless, the *Corpus Aristotelicum* omits some of Aristotle's works and includes some works that likely were not written by Aristotle himself. Moreover, it is essential to bear in mind that even the works presumed to be authored by Aristotle himself may not be complete, may include redundant parts, or may not have been arranged by Aristotle in the manner in which they have come down to us. All these phenomena can ultimately be traced back to historical contingencies that contributed to the compilation of the *Corpus Aristotelicum*—centuries after the author's passing away and without his explicit endorsement.

2.1. Not Everything Is Included in the *Corpus Aristotelicum*

Our assumptions about what Aristotle might have actually written mainly depend on three types of sources: ancient catalogs of Aristotle's writings, references or quotations from later ancient authors, and Aristotle's cross-references to his own non-extant works. According to all these sources, there were works ascribed to or written by Aristotle that are absent from the *Corpus Aristotelicum*. In numerous instances of works mentioned in the ancient catalogs, we possess only the titles of the lost, supposedly Aristotelian works. In some cases, we can glean clues about the presumed subject matter of the listed works, for example, when ancient authors mention that a specific theme or thesis can be found in a certain work by Aristotle. In more fortunate (albeit comparatively rare) cases, we have substantial accounts of the content of some of the lost Aristotelian works. In certain other instances, we even have verbatim quotations from these works; only the latter case can be termed a "fragment" in the strict sense.

There are three extant ancient catalogs of Aristotle's works,[1] two of which rely on an earlier, one on a later inventory. The earlier inventory that is used by Diogenes Laertius and by Hesychius seems to originate from Hellenistic times, possibly drawn up for the Library of Alexandria, established after the death of Alexander the Great, in the late fourth or early third century BC. The catalog that is presented by Diogenes Laertius as a segment of his biography of Aristotle (5.22–27) mentions 141 titles and often notes the number of books composing each particular work: "*On Justice*: 4 books, *On Poets*: 3 books, *On Philosophy*: 3 books . . . ," and so on. At the catalog's conclusion, Diogenes tallies this to a sum of 445,270 lines—without even mentioning some of the works most cherished by modern readers. (As a comparison, the modern Bekker edition contains around 100,000 lines in roughly 3,000 columns.) Hesychius is the author of another ancient biography of Aristotle, the so-called *Vita Hesychii*, which also includes a catalog

1. These are included in the Catalogs of Aristotle's Writings in Volume 2.

of Aristotle's writings. It confirms many of the titles mentioned in Diogenes, but it also lists some additional titles of works ascribed to Aristotle, amounting to a total of 185 titles. Yet the presence of a title in one of these two lists is not sufficient evidence of the work's authenticity—particularly as these lists might encompass both works by Aristotle and those authored within Aristotle's school. Still, these lists do provide some evidence that the collection featured in the *Corpus Aristotelicum* is far from comprehensive.

Some of Aristotle's lost works mentioned in the ancient catalogs were unmistakably dialogs: *On Philosophy*, *Sophist*, *On Prayer*, *On Rhetoric* or *Grylus*, *On Justice*, *On Love*, and more. Arguably, these were intended for publication and, much like the renowned dialogs of Plato, aimed at engaging a wider audience, possibly for the dissemination of Platonic-Aristotelian doctrines. Assuming that these catered to readers' needs and their limited philosophical expertise, a distinct contrast seems to emerge between them (none of which have survived as a whole), on one hand, and the Aristotelian treatises preserved in the *Corpus Aristotelicum*, on the other. Many texts in the latter group are quite dense and were presumably composed for an expert audience or in a teaching context, making them rather challenging to approach.

Consequently, it has become customary to distinguish between Aristotle's published, exoteric works (which are lost) and the preserved treatises primarily intended for internal academic purposes within a didactic curriculum (also known as "acroamatic," that is, designed for hearing only) possibly never intended for publication.[2] However, this overarching picture demands several caveats. Most notably, significant differences exist regarding the intended readership even within the *Corpus Aristotelicum* itself.

Some writings may have indeed functioned as lecture notes (as is frequently asserted in scholarship, presupposing that readers or listeners were already familiar with specific positions and arguments the text references), other writings adopt a more accessible style (for example, the initial books of the *Nicomachean Ethics*). Others, like Books 7 and 8 of the *Politics*, delve into practical matters—for example, whether settlers should choose coastal or mountainous areas, or discussing the recommended quantity of wine for toddlers—that are presumably of general interest and are, in any case, readily accessible. Throughout his ethical treatises, indeed, Aristotle emphasizes that his intent is not merely to understand happiness and virtue but also to contribute to effective legislation and to facilitate the genuine attainment of virtue and happiness.

Likewise, the *Rhetoric* is not solely concerned with understanding the nature of persuasion but also equips individuals for courtroom defense or successful participation in the citizen assembly. Moreover, although Aristotle's extant works on philosophy of nature envision a comprehensive, coherent project aimed at encompassing nearly all facets of the perceptible and moving world, thus appealing to advanced philosophy students, some of his logical works introduce basic techniques of proof and argumentation and seem more suitable for learners at a foundational level.

2. See Aulus Gellius, *Attic Nights* 20.5.11–12.

In essence, then, while it is true that the treatises included in *Corpus Aristotelicum* are not "exoteric" or "mainstream" in the same sense as the lost dialogs presumably were, yet they are not all alike and do not uniformly cater to purely academic interests.

A considerable number of the lost texts, though they were not published dialogs, do seem more generally accessible. Notably, there is a group deserving special mention: those related to the history of philosophy and the crafts. For instance, Aristotle appears to have composed treatises on the doctrines of the Pythagoreans, Democritus, the Academic philosophers Speusippus and Xenocrates, and Plato's doctrine of eternal Forms. In the latter case, we are fortunate that Alexander of Aphrodisias, the most influential ancient Aristotle commentator, found it beneficial to quote from these treatises in order to shed light on Aristotle's succinct arguments against the assumption of Forms in *Metaphysics* 1. Through Alexander's quotations, we can reconstruct significant portions of Aristotle's lost treatise *Peri Ideôn* or *On Forms* (F172–175), offering insight into how such short treatises might relate to his major works such as the *Metaphysics*.

In this treatise Aristotle appears to compile and systematize arguments used by Plato and Platonists to establish the existence of eternal Forms and Aristotle's objections to them. As a result, Aristotle's refutation of Plato's doctrines in the *Metaphysics* can be concise, only referencing "the arguments from the sciences," "the one over many," and so on, and recalling that these arguments are untenable due to the objections established elsewhere. Consequently, it is possible that some lost treatises on the history of philosophy and the crafts served as material collections for Aristotle, potentially echoing within his extant major works.

2.2. The *Corpus Aristotelicum* Includes More Than It Should

Whereas many of the titles mentioned in the ancient catalogs do not align with any of the transmitted works as we know them, the *Corpus* also incorporates several treatises that seem to be misplaced here. Scholars call these works "dubious" or "spurious," indicating that it is uncertain whether Aristotle actually authored them or that it is relatively clear that he did not. How did these works find their way into it?

First, it is crucial to recognize that even the spurious works are not unrelated to the Aristotelian oeuvre; all of them, to some extent, are connected either to the Aristotelian school or the authentic part of Aristotle's oeuvre. They might have been written by members of Aristotle's school or other Aristotelian philosophers. It is unsurprising that these treatises featured Aristotelian terminology and theories, leading ancient editors to accept them as works authored by Aristotle. Furthermore, it seems that in his effort to construct a comprehensive philosophical worldview, Aristotle assigned various sub-projects to his students. For instance, certain collections ascribed to Aristotle, such as the collection of political constitutions, the compilation of winners' names from the Pythian games in Delphi (F219), and the compilation of rhetorical manuals (F158–163), might have been joint endeavors.

Likewise, some of the spurious works might have emerged from such commissioned or collaborative projects—close enough to be attributed to Aristotle, yet on closer examination, distinctly divergent. Further, some clearly spurious treatises might have been included in the *Corpus* due to their titles being mentioned in the early ancient catalogs of Aristotelian writings (for example, *Mechanics*, *Economics*, *Against the Doctrines of Melissus*, *Against the Doctrines of Xenophanes*, *Against the Doctrines of Gorgias*).

In his extant works, Aristotle refers to a treatise called *Problemata* several times. There are two treatises in the *Corpus Aristotelicum* that could potentially correspond to this reference: *Problemata Physica* and *Problemata Mechanica* (often referred to simply as the *Mechanica* or *Mechanics*). However, both these treatises seem to incorporate later material, probably influenced by Aristotle's student and friend Theophrastus. This explains why an ancient editor might have included them in Aristotle's oeuvre, even though the work Aristotle himself referred to seems to be lost or was never completed.

Another example is the *Rhetoric to Alexander*, a comprehensive manual of rhetoric, whose core tenets are, however, entirely unrelated to Aristotle's own three books on the *Rhetoric*. Ancient editors might have incorporated it due to a faked dedication letter, where the author impersonates Aristotle, dedicating the subsequent book to his former pupil, Alexander the Great.

The enigmatic treatise *On Marvelous Things Heard* oddly present in the *Corpus Aristotelicum* recounts sensational fairy tales (what we nowadays call "paradoxography")—far from Aristotle's sober scientific approach. The point is, however, that some of these tales are derived from Aristotle's *Historia Animalium*, though quoted out of context. The presence of a connection with an Aristotelian treatise might have sufficed for its inclusion in the Aristotelian canon.

How can we identify a work in the *Corpus Aristotelicum* as spurious? The authenticity of many of these suspicious works has always been a topic of scholarly dispute. While debates about authenticity or inauthenticity have been resolved for the most part, a few dubious works still generate ongoing disputes, notably, the work called the *Magna Moralia*, and at times the *Economics* and the *Mechanics* have found advocates for their authenticity.

Scholars rely on clues such as cross-references to or from works believed to be Aristotelian and on terminological and doctrinal consistency with works known to present core Aristotelian doctrines. For instance, the small treatise *On Breath* displays an intimate familiarity with Aristotle's biological theories, yet in some aspects, it posits claims that are in direct conflict with Aristotle's statements elsewhere. The spurious treatise *On Virtues and Vices* presents an Aristotelian list of virtues and was thus included in the Aristotelian canon. However, it reveals its inconsistency by incorporating this list of virtues into the Platonic, not Aristotelian, theory of the soul. The *Magna Moralia* reiterates numerous core doctrines from Aristotle's *Eudemian* and *Nicomachean Ethics*, but a minute detail concerning the Greek dialect within this treatise presents a non-negligible problem: while Aristotle consistently employs the formulation *peri tinos* for "about something," the author of *Magna Moralia* uses the alternative, and likely later,

formulation *huper tinos*, which coincidentally echoes the idiom of Aristotle's student Theophrastus.

2.3. Some Works Might Have Been Differently Arranged

The question of authenticity has to be distinguished from the question of who is responsible for the arrangement and editions of the Aristotelian works as we know them. The *Corpus* presents us modern readers with complex works consisting of artfully connected individual books: the *Prior* and the *Posterior Analytics* consist of two books each, the *Topics* of eight books, the *Physics* of eight books, the *Metaphysics* of fourteen books, the *Rhetoric* of three books, the *Meteorology* of four books, the *Historia Animalium* of nine books, the *Eudemian Ethics* of eight, the *Nicomachean Ethics* of ten books, and so on. More often than not, an individual Aristotelian book that has come down to us as part of a complex work, such as the individual books of the *Metaphysics* or of the *Nicomachean Ethics*, presents a relatively self-contained philosophical unit or, ultimately, a distinctive step within an ongoing agenda—just as the individual chapters in a modern philosophical book are supposed to do (sometimes, however, one unified project extends over more than one book—for example, the treatment of friendship in the *Nicomachean Ethics* covers Books 8 and 9).

In many cases the composition of complex works out of several such individual books makes perfect sense, even though it is likely that the final arrangement of the individual books was the achievement of the ancient editors and not Aristotle's own work. Often the texts of the individual books contain indications about a particular book's standing within a more comprehensive work—for example, they indicate what topic has to be treated next or they refer back to what has previously been established. This is why the ancient editors could not invent major works, such as the *Metaphysics* or the *Nicomachean Ethics*, from scratch, but had to be faithful to the indications given in the Aristotelian texts. Sometimes, though, it seems that there are ill-embedded forward or backward references or editorial signposts—for example, "having dealt with such-and-such," "we have to deal with so-and-so next"—that have not been inserted by Aristotle, but by the editors, thus justifying their independently formed editorial decisions.

Still, even though for the most part the arrangements of individual books were conducted with a view to the philosophical agenda and to indications given in the texts, it seems that there was ample room for editorial decisions and, hence, also for bad decisions. Why, for example, was the *Metaphysics* equipped not with one, but with two introductions, *Metaphysics* 1 and 2? Similarly, *Physics* 1 and 2 could have served as alternative introductions to the study of nature. If one of the two ethical treatises, the *Eudemian* and the *Nicomachean Ethics*, was meant to replace the other, why do they have three books in common? Apparently, this is due to decisions made by ancient editors, who noticed a philosophical lacuna in one of the two treatises and tried to fill the gap by inserting books from the other treatise. Why is it that the *Metaphysics* includes

one book, namely, Book 11, that consists of transcripts and excerpts from other books of the *Metaphysics* and the *Physics*?

There are many such examples in the Aristotelian oeuvre. Sometimes it is the inclusion of a particular book into a more complex work that seems to be suspicious, sometimes our puzzlement concerns the position of a particular book or chapter within a more comprehensive context. Often one gets the impression that the ancient editors were keen to arrange all the thematically related or seemingly related material they received into one and the same work: all the physical texts went into the *Physics*, all political books into the *Politics*, all metaphysical stuff into the *Metaphysics*. This is understandable from the perspective of the ancient editors, since, after all, they did not want to lose or exclude any material they took to derive from the great philosopher.

We have good reason, then, to be cautious in accepting a certain arrangement or order of individual books or chapters, because they might be the result, not of the author's intention, but of an intervention by the editors. However, this does not mean that the transmitted arrangement is merely arbitrary. It often seems, as already indicated, that the individual books fit together in a quite natural way and sometimes it is even indicated in the Aristotelian texts how the several treatises are meant to be interconnected. To some extent, it seems to be a matter of scholarly preferences or changing methodological fashions whether the unity of a complex work or the independence of its individual books and sub-projects is emphasized. At any rate, it is wise to keep in mind that while modern authors have to give their imprimatur prior to the publication of their works, Aristotle never had this opportunity. Most of the works included in the *Corpus* were probably never meant for publication, others might have been a work in progress that was continuously revised, and others were probably left unfinished at the time of Aristotle's premature death. The rest is the work of the ancient editors, which might be considered as both a blessing and a curse.

2.4. The Composition of the *Corpus Aristotelicum*: Hints and Guesses

Who were these ominous ancient editors and how was the *Corpus* compiled? Here are some hints and guesses. The rather uncontroversial part of this story concerns the influence of Andronicus, an Aristotelian philosopher from Rhodes who came to live either in Rome or in Athens. He is traditionally supposed to be responsible, to some extent, for the collection and arrangement of works that make up the *Corpus*.

According to the geographer Strabo (*Geographica* 13.1.54), Aristotle's most important student, Theophrastus, bequeathed his library, which also contained the writings of Aristotle, to his student Neleus. Neleus again sold one part of this collection to the Library of Alexandria, but took the remaining part to Scepsis in Asia Minor, his hometown, where it was kept by some of his descendants. Later, in the early first century BC, this part of Aristotle's writings was sold to the bibliophile Athenian Apellicon of Teos. After the occupation of Athens by the Roman general Sulla (86 BC), the manuscripts were

brought to Rome, where the grammarian Tyrannio (with whom Cicero was personally acquainted) assumed care of them. From Tyrannio they were passed on to Andronicus, as attested by Plutarch (*Sulla* 26) and Porphyry (*Vita Plotini* 24.9–11).

Porphyry credits Andronicus with organizing the transmitted material by collecting related material and distinguishing the several treatises. An additional piece of evidence for the impact of Andronicus is the catalog, preserved only in Arabic, was composed by Ptolemy-el-Garib. Ptolemy claimed that he possessed Andronicus' writings and that his catalog is based on Andronicus'. It seems therefore clear that Andronicus played an important role in the composition or edition of Aristotle's works.

What exactly his contribution to the formation of the *Corpus* was is less clear. However, there is a remarkable difference between the two earlier Hellenistic catalogs, which were prior to Andronicus' intervention, and the later catalog by Ptolemy, which presupposes Andronicus' edition. The earlier catalogs list many titles, but they are silent about some works that are included in our *Corpus*. Most notably, they do not mention Aristotle's biological works (with the exception of *On the History of Animals*). The later catalog of Ptolemy, by contrast, mentions almost all works in our *Corpus* and lists them in a row (29–54) as one coherent block. In addition, it almost always mentions the number of books of each work that we know from our editions.

Given that major works from our *Corpus* were absent from the two earlier lists (by Diogenes and Hesychius) or were not presented as a unit, and given that the later list presents an organized sequence of works that essentially resembles our *Corpus*, it is tempting to think that it was mostly due to Andronicus' intervention that this compilation came about. At any rate, even if we doubt that this was the work of one single editor, we can say that in the second century AD, Alexander of Aphrodisias commented only on those works of Aristotle that are included in our *Corpus*, which seems to indicate, first, that he had a version of this collection that is close to ours, and second, that he regarded the works in it as the most important works (he knew of other works by Aristotle as well, but used them only to shed light on the works included in the *Corpus*). So what we can say is that our *Corpus*, or a version similar to it, was formed between the first century BC and the second century AD—if not by Andronicus alone, then by editors who lived and worked after Andronicus, but before Alexander of Aphrodisias.

The achievement of Andronicus thus probably consists in presenting Aristotle's work as a well-organized system including several thematic groups that somehow build on each other. But he was likely not an editor in the modern sense, in the sense of attempting to provide an authoritative text based on the comparison of all available manuscripts.

It is difficult to get beyond this still relatively meager result. A lot depends on the credibility of the report by Strabo, who wishes to explain the temporary decline of Peripatetic philosophy after Theophrastus' death by the inaccessibility of the Aristotelian writings as well as the renewed interest in Aristotle in his own days by the eventual recovery of his work. In particular, Strabo's claim that Aristotle's main works were kept in a trench in Scepsis and thus became unavailable raises a difficult question: Did the Aristotelians who ran the Peripatetic school in Athens or the Aristotelians on the island

of Rhodes (to which Aristotle's student Eudemus retreated) really not keep any copies of the main works? This is one reason why many scholars find this part of Strabo's report just untrustworthy. Nonetheless, it remains true that the main changes between the ancient catalogs before and after Andronicus concern some of the works of our *Corpus Aristotelicum* that were not even mentioned in the earlier catalogs.

2.5. Bekker's Edition of the *Corpus Aristotelicum*

Immanuel Bekker's first critical edition of Aristotle's works (1831) includes all and only works that were part of the received *Corpus Aristotelicum*. It thus collects the same writings that were already included in the *Aldina*, except, as we saw, that Bekker includes the *Rhetoric* and the *Poetics*, while the *Aldina* did not. Bekker also kept the order of the works that the *Aldina* had used, together with the thematic grouping of Aristotle's works into four or five major thematic blocks:

1. logic and theory of argumentation,
2. philosophy of nature,
3. primary philosophy (metaphysics),
4. ethics and political theory, and
5. rhetoric and poetics (Bekker).

This scheme was essentially predetermined by the order and arrangement of the titles initiated by Andronicus and documented in Ptolemy, the only difference being that in the ancient catalog the fourth and the fifth group (that is, those including ethics, politics, rhetoric, and poetics) were positioned after the logic group and before the philosophy-of-nature group.

The following table lists in order all the writings included in Bekker: works thought to be dubious are marked with †, those thought to be spurious ones with ††. The customary Latinized titles (together with the Bekker pagination) provide an internationally usable system of reference. In most cases the English titles that are nowadays in use are translations or transpositions from the Latin. But it is not clear whether all these titles are Aristotle's, since sometimes the titles are derived from the first lines of a treatise or from their agenda, so that they qualify as proper "designators," but might not have been officially imposed as titles.

The *Organon*: Logic, semantics, theory of argumentation and proof

Categoriae	*Categories*	$1^{a}1–15^{b}33$
De Interpretatione	*On Interpretation*	$16^{a}1–24^{b}9$

Poetica	*Poetics*	1447^{a}8–1462^{b}18

2.6. Writings That Did Not Make It into Bekker's Edition

What has not been transmitted as a complete treatise within the *Corpus* was not included in Bekker's edition. The rest of Aristotle's (mostly lost) writings are traditionally treated as fragments. Collecting and editing these is less straightforward than editing writings included in the *Corpus*, for it is often controversial which reports by later authors should be taken as genuine and which can qualify even as verbatim quotations. Also, the number of references to Aristotle's works in antiquity is quite extensive. Where to start and where to end?

Nonetheless, after the completion of Bekker's edition, the Prussian Academy in Berlin offered a research award for the best study on Aristotle's fragments (although the collection of Aristotelian fragments was no longer uncharted territory by this time: the Istrian humanist Franciscus Patricius published the first systematic collection of Aristotelian fragments as early as 1571).

In the competition that followed, the librarian Valentin Rose, the author of a doctoral thesis from 1854 that tried to prove that all the reported or fragmentary works not included in the *Corpus Aristotelicum* are spurious, won the first prize. It was titled *Aristoteles Pseudepigraphus* and included a preliminary collection of Aristotelian fragments, although the author repeated and reinforced his old thesis that all the treatises to which these fragments are assigned are spurious. The printing of this treatise was financed by the Prussian Academy in 1863 and is known as R^1.

Although Immanuel Bekker and other members of the editorial board disagreed with Rose's main thesis, they printed an abbreviated version of his collection of fragments in the fifth volume of the Academy edition (in addition to the two volumes that include Bekker's edition, the third and fourth volumes were dedicated to the Latin translation of Aristotle and to the scholia, that is, short commentaries from the margins of the manuscripts). This fifth volume was published in 1870 and is referred to as R^2. In order to document his skepticism, Rose called his work *Aristotelis qui ferebantur librorum fragmenta*—"fragments of books which were transmitted as Aristotelian works." Between the competition and publication of the fifth volume of the Academy edition, Emil Heitz, the person who was ranked in the competition behind Rose, had published a (quite plausible) refutation of Rose's claims about the inauthenticity of the lost works assigned to Aristotle and had published his own collection of the fragments in France.[3] Finally, Rose published an improved and separate edition of the fragments in the more easily accessible *Teubneriana* series. It was published in 1886 and is referred to as R^3. There is a certain irony in the fact that the most famous editor of Aristotle's fragments, who dedicated most of his scholarly life to this topic, never believed in the authenticity of what he collected.

More recently, scholarship has focused on selected lost or recovered works that seem to be particularly rewarding from a philosophical point of view. Three or four examples deserve to be highlighted. An important addition to the metaphysical treatise preserved in the *Corpus Aristotelicum* is the small treatise *On Forms*, important parts of which could be reconstructed from ancient commentaries on Aristotle's *Metaphysics*, in particular from Alexander of Aphrodisias. The retrieved text turned out to be one of the most significant testimonies for the Academic discussion about Plato's assumption of eternal Forms.

Another example of indirect transmission is Aristotle's *Protrepticus*, an exhortation to philosophy, in which Aristotle promotes the benefits of philosophy as he understands it. This is one of the few examples of how an exoteric Aristotelian text, one that

3. *Fragmenta Aristotelis*, collegit disposuit illustravit Aemilius Heitz (Paris, 1869).

explicitly addresses a broader public, might have looked. An important source for the reconstruction of this text is Iamblichus, who lived in the third and fourth centuries AD. Iamblichus compiled exhortative arguments from several authors without indicating which particular author he is referring to or quoting from. In 1869 Ingram Bywater first formulated the thesis that major parts of Iamblichus' *Protrepticus* were taken from Aristotle.[4] Even though Bywater's thesis has been largely accepted and the *Protrepticus* has been widely acknowledged as a quotable work of Aristotle's (in addition to the fragments edited by Rose), it is also an example of how difficult it is to reach scholarly agreement on the detailed reconstruction of a lost treatise, for it turned out to be notoriously difficult to determine which particular arguments in Iamblichus were taken from Aristotle and which were not.

A rather intricate and, to some extent, disappointing example of the hunt for Aristotelian fragments is provided by Aristotle's announced treatment of comedy. Aristotle himself refers several times to his discussion of the comical and laughable, but his *Poetics*, as it has come down to us, includes only a treatment of epic and tragedy. We have to conclude, then, that the *Poetics* originally included a second book (which is mentioned in Diogenes' catalog) which included an extended discussion of comedy, but that this second book is lost. That of all Aristotelian writings the treatment of the comical and of laughter is lost has been the stuff of crime stories and conspiracy theories. Scholars kept browsing ancient texts for hints on Aristotle's views about comedy. A manuscript from the tenth century AD, commonly referred to as *Tractatus Coislinianus* (F167), was suspected of including a summary of Aristotle's theory of the comedy, but no scholarly consensus has been reached.

While in the case of the other lost works of Aristotle scholars count themselves lucky when they are able to identify one or a few genuinely Aristotelian lines in later works, it was possible to regain almost the entirety of the treatise *The Athenian Constitution* from papyri found in the late nineteenth century (and, hence, after Rose's edition of the fragments). In this treatise the author gives a historical and systematic description of the development of the constitution of Athens down to Aristotle's time. Most likely this treatise was part of the collection of 158 constitutions mentioned by Diogenes Laertius and by Aristotle himself (*NE* 1181^{b}15–24) as a starting point for his own philosophical inquiry into political constitutions in the *Politics*.

The case of *The Athenian Constitution* is unique: not only is it the longest continuous text from the supposedly Aristotelian writings that were not transmitted within the *Corpus Aristotelicum*, it is also the only text under the name of Aristotle that is directly edited from an ancient papyrus. It still might be, however, that this treatise was compiled not by Aristotle himself, but by members of the Aristotelian school as part of the more comprehensive project of collecting constitutions from various cities. Indeed, scholars have observed in this treatise traces of what they took to be stylistic and terminological differences to other Aristotelian works. Besides, it has always been suspected that it was

4. "On a Lost Dialogue of Aristotle," *The Journal of Philology* 2 (1869): 55–69.

simply impossible for one single person (even for a person as prolific as Aristotle) to draft the collection of all 158 constitutions by himself.

3. Aristotle's Philosophical Oeuvre: A Survey

The most amazing thing about Aristotle is the fact that his philosophy is not centered on one specific thesis or one specific field—or even a few of them—but combines topics as divergent as logic, zoology, meteorology, political theory, and metaphysics, to mention just a few examples. His achievements in these various fields are quite different in character and cannot be subsumed under one particular slogan or claim. This first impression seems to comply with what Aristotle himself thought about philosophy and the sciences, namely, that distinct parts of philosophy and distinct sciences differ in accord with their specific subject matter and require different standards of exactness. He programmatically objected to attempts of some of his predecessors to sketch a grand unified discipline that is supposed to incorporate scientific knowledge of all possible subject matters alike. Accordingly, Aristotle's own philosophy and scientific research are subdivided into different and more or less independent fields; and it is not by chance that these different fields are characterized by different kinds of findings and philosophical methods.

In order to get a first synoptic view, it is useful to follow the traditional subdivision of Aristotle's oeuvre (Section 2 above), which distinguished roughly between logic, philosophy of nature, metaphysics, ethics and politics, and, somewhat awkwardly, rhetoric and poetics. To some extent, this division is backed by what Aristotle himself says, when he distinguishes theoretical, practical, and productive sciences (*Met.* 1025^{b}25, *NE* 1139^{a}27–28, *Top.* 145^{a}15), if we suppose that philosophy of nature and primary philosophy are both theoretical, ethics and politics practical, and rhetoric and poetics productive sciences or crafts. Aristotle also acknowledges that theoretical science can be further subdivided into, roughly, the study of nature, dealing with what is movable and has matter, and the study of what is neither movable nor has matter, which, according to Aristotle, falls to mathematics (whenever these objects are ontologically dependent) and to primary philosophy (whenever these objects are ontologically independent).

Philosophy of nature, broadly conceived, makes up almost the half of the *Corpus*. It might be further subdivided into, first, the *Physics* and all treatises that deal with the superlunary natural world, the atmosphere, and the elements; second, the works that deal with psychology, that is, the soul and psychic capacities and functions that are common to body and soul; and, third, Aristotle's biological work, which, taken by itself, makes up almost one-quarter of his transmitted work.

While Aristotle does not have a single word for what we call "logic," he acknowledges that some of his treatises are topic-neutral and have no definite subject matter, so

that they are not captured by the scheme of theoretical-practical-productive. These are the treatises included in the *Organon*.

3.1. The Works Traditionally Assigned to the *Organon*

The group of treatises that is printed first in all editions of Aristotle's works is traditionally called the *Organon*, which means "instrument" or "tool," in the sense of an instrument for or propaedeutic to philosophy and science. It comprises six treatises: the *Categories*, *De Interpretatione*, *Prior Analytics*, *Posterior Analytics*, *Topics*, and *Sophistical Refutations*. All these (with, at least, one notable exception) deal with arguments and argumentation. Since the Greek word for argument is *logos*, the treatises in the *Organon* might be called "logical" in the broad sense of "pertaining to arguments and their elements," but not all of them pertain to formal logic. Likewise, since the treatises of the *Organon* present different methods of inquiry related to the different types of arguments (for example, the method of dialectic related to dialectical and the scientific method related to scientific arguments), they are often described as methodological.

That is what most scholars can easily agree on. The problem is that Aristotle himself does not refer to the subject of these treatises in such terms. For though he is the inventor of the first system of formalized logic, he does not have the notion of logic either in the broad or in the narrow sense. In one passage (*Top.* $105^{b}19$–25) he says that all premises and problems discussed in a dialectical disputation are either natural-scientific, ethical, or "logico-linguistic," which, at first glance, looks very much like the Stoic division of philosophy into physics, ethics, and logic. However, the sole example here of a logico-linguistic problem is whether or not there is one single science of each pair of contraries. And this clearly shows that it is not our notion of logic he has in mind.

One must also keep in mind that the label *Organon* for these works is a later invention and reflects the views of later ancient Aristotelians who opposed the Stoic idea that logic is one of the three parts of philosophy (see Diogenes Laertius 5.28). This concept of an *organon* suggests that the inquiries in these treatises are (just) propaedeutic to what Aristotle is doing in his own scientific and philosophical works. In some respects, this would have been acceptable to him. Most notably, in the *Posterior Analytics* he formulates his conception of a scientific proof and, even though it is not always easy to detect explicitly formulated proofs in his scientific works, modern scholars have made great efforts to show that parts of his scientific treatises do aim to formulate such proofs. In this respect it is simply true that the inquiry into scientific proofs as such is meant to be preparatory and propaedeutic to the practice of Aristotle's own scientific-philosophical research (and, perhaps, by his lights, to any future research). It is in the same spirit that, for example, the Neoplatonic schools of late antiquity used the *Organon* for introducing students to the method(s) of philosophizing quite generally.

Aristotle himself also occasionally appeals to the idea of a scientific-philosophical propaedeutic. This is concealed in what he says about *paideia*, a general form of educatedness with regard to sciences and the use of proofs, and so forth (see *PA* $639^{a}4$–6,

NE 1094^{b}23–27, *Met.* 994^{b}32–995^{a}17, 1005^{b}2–5). He distinguishes this general educatedness from accomplishments in particular sciences; the failure to be educated in this way is manifest in the tendency to demand proofs for what cannot be proved or to demand a degree of precision that is unreachable in a given domain—for example, looking for mathematical exactness in the study of human affairs. Arguably, it is the study of certain parts of the *Organon* that can prevent people from committing these mistakes.

It would thus not be outlandish for Aristotle to regard (parts of) the *Organon* as propaedeutic for what he is ultimately most interested in: moral philosophy, philosophy of nature, and primary philosophy. Still, the idea of being "merely propaedeutic" or "merely instrumental" to something else includes a value statement about the allegedly inferior status of the studies contained in the *Organon* that Aristotle himself nowhere explicitly makes. And modern scholars, who regard, for example, Aristotle's invention of syllogistic logic in the *Prior Analytics* as his most remarkable (and, perhaps, least controversial) achievement, would be particularly reluctant to accept such a derogatory statement.

How else can we account for the unity of the various sub-projects of the *Organon*? As we saw, the occupation with arguments seems to provide a common thread to (most of) these treatises. Arguments, Aristotle states, are either inductive or deductive (*Top.* 1.12). An inductive argument proceeds from particulars to something general (105^{a}13–16): if, for example, the pilot who has knowledge is the best (pilot), and the charioteer who has knowledge is the best (charioteer), then generally the one who has knowledge (in each field) is the best. A deduction, by contrast (*Top.* 100^{a}25–27, *APr.* 24^{b}18–20), is an argument in which certain things being assumed (the premises), something different (the conclusion) follows by necessity through the assumed premises. This latter type of argument receives the greatest attention not only in the *Prior* and *Posterior Analytics*, but also in the *Topics* and the *Sophistical Refutations*. It is regularly illustrated by the following example: all humans are mortal; all Greeks are humans (premises); therefore, all Greeks are mortal (conclusion). Deductive arguments of this form have come to be known as "syllogisms," which is the anglicized version of the Greek *sullogismos*.

It is common to all well-formed syllogisms that the conclusion follows from the assumption of the premises alone. By looking into the premises of such arguments and, in particular, their epistemic status, one can derive an important classification of all syllogisms. Suppose that the premises of an argument express views that are not (yet) firmly established but are accepted either by all or by many or by the most renowned experts (which is to say that they are "acceptable beliefs"). In this case, Aristotle stipulates, the argument is dialectical. If, by contrast, the premises are (established as) true and primary in the sense that they are credible in themselves and do not receive their credibility through anything else, then the argument can qualify as a demonstration or scientific proof, conveying genuine knowledge.

Dialectical arguments, on the one hand, and demonstrative arguments, on the other, are indicative of two main branches of inquiry that Aristotle defines: dialectic, which serves to examine opinions on all subject matters (systematically developed in Aristotle's

Topics), and scientific argumentation, which is meant to account for certain regularly occurring phenomena by relating them to their specific explanatory starting-points (most explicitly developed in the *Posterior Analytics*).

This latter demonstrative method is grounded in Aristotle's notion of unconditional scientific knowledge, according to which we know each thing when we know the cause due to which it is necessarily the case (*APo.* 71^{b}9–12). The demonstration refers the phenomenon to be known (mentioned in the conclusion) back to the starting-points (mentioned in the premises) that give us the explanation for why the phenomenon in question is the case. Often, in his scientific work, Aristotle aims, for example, at demonstrating that certain intrinsic coincidents (often referred to as "*per se* accidents") belong to a certain class of subjects either in virtue of the nature or essence of the subjects in question or in virtue of the affections' nature or essence. Once this has been demonstrated, one knows why it is the case that these particular types of affection belong to this particular type of subject and that the former belong to the latter by necessity.

We thus see the major division between dialectical and demonstrative arguments, which is important not only for the structure of the *Organon* but also for Aristotle's scientific and philosophical methods in general. Such arguments are genuine syllogisms, meaning they actually deduce what they claim to deduce. In contrast, when arguments appear to be deductions but fail to deduce what they seem to, they are fallacies. Aristotle studies these in the *Sophistical Refutations*. A particular claim (or the person making the claim) is refuted when the contradictorily opposed claim is successfully deduced. Some people (whom Aristotle calls "eristic" or "sophistical") specialize in refuting ordinary people's claims or convictions with questionable arguments, that is, by refutations that only appear to deduce the opposite of the original claim. In *Sophistical Refutations*, Aristotle identifies thirteen types of fallacies corresponding to thirteen ways of failing to be a genuine deduction. For example, an argument fails to be a genuine deduction when it uses the same word in the premises and the conclusion but with different meanings. Dialectically inexperienced addressees might fail to notice the ambiguity and hence be misled into thinking that they have been genuinely refuted.

What, then, is common to all genuine syllogisms, that is, all those whose conclusions actually follow by necessity from the premises assumed? Aristotle's great logical innovation, known as "syllogistic theory," is to provide a general scheme by which it is possible to distinguish valid from invalid deductive arguments. This is found in his *Prior Analytics*. According to it all syllogisms consist of three assertions—two premises and one conclusion. Each assertion is of the form "S is P" or "P belongs to S," and thus involves exactly two terms. A syllogism only comes about if the two premises have one term in common, the so-called middle term, while the conclusion involves the two other terms introduced by the premises: "A belongs to every B"; "B belongs to every C"; thus "A belongs to every C." Depending on the position of the middle term, Aristotle defines three syllogistic "figures." In the example mentioned, the middle term is first in the subject-position and then in the predicate-position, and hence belongs to the first figure. When, by contrast, the middle terms are in the predicate-position or in the

subject-position, the syllogism is in the second and in the third figure, respectively. In accord with the quantity of the assertions involved (whether A belongs to every or only to some B) and whether they are affirmative or negative (A belongs to every B, A belongs to no B; A belongs to some B, A does not belong to every B), Aristotle defines for each figure the available valid modes. For example, if "smart" belongs to every philosopher and "philosopher" belongs to some authors, then "smart" belongs to some (but not to all!) authors. Also, he develops several tools for demonstrating the validity of valid modes. This is the core idea of what is known as Aristotle's "assertoric syllogistic." In addition, he developed a theory of syllogisms that are modally qualified: "A necessarily belongs to every B," "B possibly belongs to some C."

Aristotle claims that all genuine syllogisms can be traced back to the syllogistic figures (and the valid modes within them). But, as a matter of fact, many of the arguments he presents (even within the *Organon*) are not in syllogistic form as they stand, even though they seem to be proper deductive arguments. Perhaps they must be rephrased in order to show that they are exemplifications of one of the syllogistic figures and modes. Nonetheless, it is still remarkable that certain treatises in the *Organon*, in particular the *Topics* and the *Sophistical Refutations* (perhaps together with the *Rhetoric*), though dealing with deductive arguments, are totally unconcerned with syllogisms of the canonical form we looked at.

This poses a puzzle for the unity and coherence of the *Organon*. If syllogistic theory was indeed Aristotle's biggest innovation in the field of logic, why are some of his works completely silent about it? This is one of those occasions on which modern Aristotle scholars start flirting with so-called developmental hypotheses, by postulating philosophical development on Aristotle's part in order to account for what they take to be inconsistencies in his oeuvre. In the given case, one might hypothesize that certain works were completed before he invented the syllogistic theory and that he afterward failed to revise them in light of the new discovery. This is one way to deal with the puzzle. Alternatively, it has been suggested that those treatises—regardless of when they were composed—could easily do without syllogistic theory owing to their peculiar purpose, which is different from the one of the *Prior Analytics*. For a long time, for example, interpreters have assumed that the method provided by the *Topics* just serves the (heuristic) purpose of finding arguments and, in particular, suitable premises.

What about the two remaining treatises, the *De Interpretatione* and the *Categories*? *De Interpretatione* is mostly concerned with what makes up assertoric sentences, affirmations and negations, their quantities, and the fact that they are contradictorily opposed. It formulates the important rule that of the two members of a contradictory pair (affirming and denying the same predicate of the same thing), one has to be true and one has to be false. Since these statements are of the same form as the premises and conclusions of a canonical syllogism, it seems natural to infer that, while the *Prior Analytics* is concerned with syllogisms, the *De Interpretatione* provides the theory of the parts of a syllogism. A similar argument has been made with regard to the *Categories*. Its core project consists in assigning each unconnected part of a proposition to one of

the ten so-called categories, that is, types of predications (and, elsewhere, also types or classes of being): what-it-is, quantity, quality, relative, when, where, position, having, doing, and being affected. While *De Interpretatione* deals with assertions, one might infer, *Categories* deals with the parts of the assertion, its terms. However, this latter claim is much more contested. For one thing, the division of the categories plays no role either in the account of assertions in *De Interpretatione* or in the theory of syllogism in *Prior Analytics*. Also, the *Analytics* provide their own account of the terms included in premises—and this account ignores the ten categories.

That is why the systematic place of the *Categories* has been a matter of dispute since the time of Andronicus (Section 2 above). Just to illustrate the problem: On the one hand, the division of the ten categories may serve as an analytic tool for assessing and criticizing competing theories—for example, someone might treat a quality (saying what something is *like*) just like a kind (saying *what* something is). This fits well with the dialectical approach of the *Topics*. For this reason, the *Categories* have been thought to be somehow attached to the *Topics*, and, as we saw, there are ancient sources using the title *What Comes before the Topics* instead of *Categories*. On the other hand, the *Categories* make some not insignificant claims, for example, about the priority of particular substances and about universals that exist only if they are instantiated or exemplified by particular substances. These are the sorts of claims that, in principle, are dealt with in Aristotle's *Metaphysics*. Still, as opposed to the *Metaphysics*, the *Categories* makes such claims as it goes along, does not argue for them, does not mention competing options, does not discuss starting-points and causes, and fails, like other treatises in the *Organon*, to speak of matter and form. It thus seems to be written in the spirit of the *Organon*—even though its exact place within this collection remains obscure.

3.2. The *Physics* and the Foundations of the Study of Nature

A considerable part of Aristotle's transmitted work is dedicated to the study of nature. The study of nature, broadly conceived, includes the discussion of discrete natural phenomena, such as celestial bodies, sublunary elements, or living beings, but also attempts to address notions fundamental to the study of nature in general. Most of Aristotle's *Physics* is dedicated to the latter project, in that it deals with the starting-points of nature and of change and movement, causality, and concepts such as nature, movement, the infinite, place, the void, time, and the continuum.

It is easy to see why a theoretical grasp on these notions might inform the study of particular natural phenomena. At the same time Aristotle's *Physics* does not confine itself to laying the foundations for studies of particular types of phenomena, but also makes and defends substantial philosophical claims connected with these notions. For example, Aristotle asserts that there is no void, that there is no actual infinite extension, that there must be an immovable mover, and so on. While, for example, Book 1 of the *Physics* accounts for the starting-points of change, by providing a scheme that can be applied to all sorts of change, and Book 3 provides a definition

applicable to all of them, Book 8 defends some of Aristotle's core doctrines about spatial movement in particular.

These doctrines include the ideas that whatever is moved is moved by something else, that each series of movers must start from something unmoved, that to guarantee eternal movement in the cosmos there must be an eternal unmoved mover, that spatial movement is primary compared to other kinds of change, that circular movement is primary among all sorts of spatial movement, and so on. These are important results for Aristotle and not just preliminaries or conceptual tools for other inquiries.

Scholars are sometimes puzzled about how to subdivide the eight books with a view to these two different directions of inquiry. Some ancient commentators have suggested ascribing the first four books to the inquiry into starting-points and the last four books to a treatise on movement, while others identified the breaking point after Book 5 and again others after Book 6 (it is agreed that the position of Book 7 within the *Physics* is doubtful, as it seems to be an independently drafted piece on topics related to it). Regardless of these subdivisions, the following are perhaps the most famous examples of how the first two books might be seen as the foundation of the study of nature.

Physics 1 announces without much introduction that it will deal with "the starting-points and causes" in the study of nature. Chapters 4–7 provide, as we saw, a set of starting-points by which it is possible to conceptualize all sorts of movement or change, thus presupposing that studying nature means studying changeable things. In each instance of movement one can distinguish a new feature that comes to be present, the opposite feature which is replaced by it, and a substrate that underlies the change (and persists through this replacement). In the case of the generation of a substance, Aristotle calls these items "form," "privation," and "matter," and it is the form and the matter that, fundamentally, qualify as the starting-points of natural substances. This is a basic tenet of the hylomorphism and pervades Aristotle's philosophy of nature and (parts of) his metaphysics, namely, that all changeable substances consist of matter and form.

Thus, if a house is to come to be, one has to assume the form of the house, its absence or privation, and something that underlies it. The generation of a house, then, proceeds from the absence of house form to the presence of the house form, and the substrate that undergoes this change (by taking on a substantial form that it did not possess before) is the matter of the house, say the bricks and stones of which the house is made. Once generated, the house therefore consists of matter and form. This hylomorphic analysis is essential for what philosophers of nature are doing and delineates their domain of study. For they are dealing with objects whose forms are necessarily "enmattered" and cannot be separated from the matter in which they occur. Aristotle often compares this to the snub, which is a concavity that occurs only in noses and in nothing else. By contrast, geometers are in some sense dealing with, for example, lines that happen to be the limits of natural bodies. But more precisely, the genuine objects of their study are lines that are abstracted away in thought from such bodies.

Physics 2 defines what "nature" means, namely, an internal starting-point of moving and being at rest, and then develops the famous division of the four types of causes,

which correspond to four different answers to a why-question. For, as Aristotle says, we do not claim to know something before we have the why or cause of it. In one way, this question can be answered by stating that from which a thing comes to be (like the bronze from which the statue comes to be). This is the material cause. In another way, it can be answered by referring to a form or paradigm, which can be captured by a definition. This is the so-called formal cause. In still another way, one might refer to the primary source of movement or rest (for example, the sculptor is the source of movement for the coming to be of a statue). This is the so-called efficient cause. Finally, one might refer to the end or purpose for which something is done—for example, when we are asked why we go for a walk and say "in order to be healthy." This is the final cause.

In his survey of the theories of previous philosophers of nature, Aristotle several times concludes that they failed to adequately account for the formal cause and incorrectly rejected the final cause. He argues that it is not possible to account for the regular and purposeful processes of coming to be and arrangements of natural things by relying on material and efficient causes alone. How can we explain, for example, that many animals grow sharp teeth at the front of the jaw and flat molars further back? Without assuming final causes, or so Aristotle argues, one would have to say that this comes about coincidentally or by luck. But this would not be sufficient to explain why this occurs always or for the most part. In Aristotle's theory of explanation, by contrast, it is plain that teeth grow this way for a purpose: the sharp teeth at the front are useful for biting off food, while the molars in the back are useful for grinding food. It is in accord with this scheme that Aristotle explains many natural phenomena.

3.3. The Study of Nature: Aristotle's Grand Plan and How It Is Executed

In *Meteorology* 1.1 Aristotle formulates a grand research plan for the study of nature, which is a good starting point for exploring the structure of his philosophy of nature:

> [1] The primary causes of nature, all natural movement, [2] the stars arranged in the upper spatial movement, [3] and the elements of bodies, how many they are and of what sorts, the change into each other, [4] and coming to be and passing away in general, have been spoken about previously. [5] It remains, then, to get a theoretical grasp on a part of this methodical inquiry, which all our predecessors have called "meteorology." It is concerned with whatever things happen in accord with nature, but a nature more disorderly, certainly, than the primary element of the bodies, and which occur in the place nearest to the spatial movement of the stars—for example, the Milky Way, comets, shooting stars, and moving and burning phenomena. It is also concerned with whatever affections may be regarded as common to air and water, and further the parts and forms of earth and the affections of the parts, on the basis of

> which we may get a theoretical grasp on the causes of winds, earthquakes, and whatever occurs in accord with their movements. [. . .] Further, it is concerned with the fall of lightning bolts, tornadoes and fire-tornadoes, and whatever other recurrent affections of these same bodies as are due to solidification. After we have discussed these things, [6] let us then get a theoretical grasp on whether we can give some account, in the way we have laid down, of animals and plants, both universally and separately. [7] For when we have stated it, all of what we deliberately chose for ourselves at the start would pretty much have reached its end. (*Mete*. 338^{a}20–339^{a}9)

Aristotle refers here to projects that correspond to some of his works on philosophy of nature, and he indicates in [7] that this project can claim some sort of exhaustiveness or completeness. Though the plan suggests a certain order among these works, this order need not be understood as a chronological order of the works' composition. It is much more likely that he wants to accommodate the new project he announces, that is, the so-called meteorology, into a system of sciences. The order of these, which is quite likely the order in which they should be studied, is determined in part by the fact that certain fields presuppose or depend on others, in that the things treaded in these fields are causally influenced by things treaded in another field. This is most obvious with regard to [1], referring to the *Physics*, which, as we saw, deals with the starting-points in the study of nature and with movement and change in general.

Section [2] introduces the sort of research that is carried out in *De Caelo* or, more precisely, in the first two books of it. These books deal with the cosmos as a whole (for example, showing that it is one and spatially limited), with the planets and stars, and with the earth. Pride of place is given to the matter of the celestial bodies, and it is argued that they cannot consist of the ordinary, sublunary elements, earth, water, air, and fire. Rather they consist of a fifth element which has a natural tendency to move in a circle. Books 3 and 4 go beyond the content he announces in section [2]. Book 3 introduces problems concerning generation and then focuses on the sublunary elements, while Book 4 deals with the heavy and the light (which are, at least, affections of the elements). The study of elements is an essential piece of Aristotle's philosophy of nature that clearly deserves its own treatise. Book 3 might be thought to deliver a part of this treatise, namely, the one on sublunary elements, Book 1 having dealt with the celestial, superlunary element.

Section [3] of the grand plan might hence either refer to *De Caelo* 3 or to *On Coming to Be and Passing Away*, a major part of which is indeed dedicated to the discussion of elements and in particular to the mutual transformation of elements that is also announced in [3]. The relation between these two works is difficult to account for, since it is not the case that *On Coming to Be and Passing Away* is merely the continuation of the discussion started in the *De Caelo.* (A further treatise of elements, their qualities and mixtures is given in *Meteorology* 4.) It is pretty likely, though, that section [4] of the grand plan refers to *On Coming to Be and Passing Away*, because in this treatise the elements are discussed against the background of a general explanation of unconditional

coming to be and passing away, that is, of substances, as opposed to mere alteration and other non-substantial changes.

Section [5] gives us a succinct summary of the main topics of *Meteorology* 1–3. The phenomena discussed there—as multifarious as they may be—fill the space between the celestial sphere and the earth (including some geological phenomena beneath the earth's surface, such as earthquakes). This intermediate position of the so-called meteorological phenomena is echoed in the sketched order of study, as the *Meteorology* comes after the study of the heavens and before the biological research that is announced in section [6]. This top-down progression is obviously intended.

One reason for this direction of research might be a certain causal or explanatory order, in that the celestial sphere clearly has an impact on what happens further down, especially in the region nearest to the movement of the stars. Similarly, concerning the discussion of elements (in *De Caelo* 3 and *On Coming to Be and Passing Away*) in relation to the agenda of the *Meteorology*, the point seems to be that the affections and capacities of sublunary elements will enter into the explanation of phenomena that it deals with. It is less clear why the study of living beings has to come afterward. But given that they live on earth (broadly speaking), they are to some extent influenced by phenomena that happen "above" them, most notably, by the course of the sun, the change of seasons leading, for example, to hibernation and migration, to growth in spring and decay in fall. But, of course, these are not the only starting-points in the study of living beings.

3.4. The Study of the Soul and of the Psychic Functions That the Soul Accomplishes Together with the Body

Aristotle's treatise *De Anima* is dedicated to a highly ambitious project. When Aristotle says in *DA* 1.1 that reaching reliable conviction about the soul is most difficult, he seems to mean it. Since the soul is the starting-point of all living beings, the treatise suggests itself as a foundational work relative to all other treatises that deal with living beings in one way or the other. Accordingly, the first chapter of *De Sensu*, the first treatise in the collection called the *Parva Naturalia* (*Short Works Pertaining to Nature*),[5] makes it clear that "what has been said about the soul . . . is to be assumed throughout" (436^{a}5), thus presenting its own project as a continuation of the *De Anima* project that makes use of the starting-point or starting-points laid down there.

The core purpose of the *De Anima* itself is to understand what the soul is and to get clear about its intrinsic coincidents (or "*per se* accidents"). Even this core project faces difficulties and challenges, some of which are immediately addressed in its first chapter. One set of difficulties is connected with the phenomenon that the soul is thought to have different parts, which seems to pose a challenge, among other things, for the unity

5. The other treatises in the first section are *On Memory and Recollection*, *On Sleep and Waking*, *On Dreams*, *On Prophecy during Sleep*, and in the second section, *On Length and Shortness of Life* and *On Youth and Old Age*, *Life and Death, and Breathing*.

of the underlying subject. More than that, one of these parts, the understanding, seems to provide such significant anomalies (most notably, it is not mixed with the body and has no organ) that it is genuinely unclear whether it can be dealt with by the part of philosophy of nature that deals with living beings. Connected with the issue of parts of the soul is an initial uncertainty about the extension of the treatise's subject matter, since previous philosophers unduly restricted the study of the soul to the study of the human soul and Aristotle is determined to overcome this—as he thinks—misleading restriction.

Due to its having different parts as well as other peculiarities, Aristotle seems to think that it is difficult to determine the what-it-is of the soul. One issue is to find the appropriate level of generality. When it comes to Aristotle's own definition of the soul in *DA* 2.1–3, he first gives an ontological classification of the soul, saying that it is in the category of substance; that, according to the scheme of the three modally defined types of substances distinguished in the middle books of the *Metaphysics*, it belongs to the form-like type of substance; and that it is on the side of actuality rather than mere potentiality, though a sort of actuality that can be more fully actualized. In the ensuing discussion, however, it quickly becomes clear that this "common account" is insufficient: it cannot adequately capture the distinctive forms of life that characterize different classes of living beings, whose starting-points of life (that is, souls) are distinct. In *DA* 2.3 he famously suggests that "it is ridiculous to inquire after a common account" of the various sorts of soul, such as nutritive and perceptual soul, "when it is an account that will not be special to any being, and will not be in accord with its proper indivisible form, to the neglect of the one that is of this sort" ($414^{b}25$–29).

Another issue is the relation between the what-it-is of the soul and its intrinsic coincidents. In a remarkable passage (*DA* $402^{b}16$–22), likely motivated by the difficulty of defining the soul, Aristotle makes the point that it is not only the case that we need the what-it-is in order to account for its intrinsic coincidents, but rather it is likewise true that a grasp of these coincidents might help us to track the what-it-is, in that we have to look for the what-it-is by inquiring into how a given set of them can best be accounted for. At the very least, this suggestion concerns the question of how a suggested what-it-is of the soul can be assessed and how its explanatory powers can be put to the test. This method seems to redirect attention to the intrinsic coincidents of the soul. However, with regard to the so-called affections of the soul we must confront the often-quoted problem (*DA* $403^{a}4$–10) that most of them do not seem to belong to the soul exclusively, but also (and perhaps more properly) to the living being, for the soul suffers or initiates none of its affections and works without the body (*DA* $403^{a}10$–11).

The precise implications of this claim are a matter of scholarly dispute. However, it seems uncontroversial that this phenomenon presents a challenge to and, perhaps, a limitation on a treatise that is dedicated to the study of the soul *as such*—since, as we saw, the beginning of the *De Sensu* refers back to *De Anima*. If the *De Anima* is restricted to the discussion of the soul as such, how specific can it get with regard to each of the types of life and, in particular, with regard to affections and activities that may come

about through the soul, but are strictly speaking affections and actions of the composite (the living being)?

This degree of specificity might concern the completeness and differentiation of the treatment of activities coming about through the soul, on the one hand, and the level of detail at which each is discussed, on the other. In the former respect not all of the activities of living beings that the first section of the *Parva Naturalia* deals with play a role in the *De Anima* (for example, sleeping, dreaming, memory); in the latter respect the *Parva Naturalia* can pick up topics that have already been discussed in the *De Anima*, but only in universal terms (for example, in *De Sensu* 3, Aristotle resumes the discussion of objects of perception that have been treated in such terms in the *De Anima*, namely, with regard to their function and the actuality of each of the perceptual organs).

Insofar as the discussion in the *De Anima* is retrospectively characterized as a study of the soul and its affections and works *as such*, it also becomes clear that there is a complimentary project dealing with these, but with a view to their bodily side or to the bodily environment in which they occur. This latter project is carried out in the *Parva Naturalia*. It is defined and announced in *De Sensu* 1 by the formula that there are activities of animals that are common to body and soul, such as "perception, memory, spirit, appetite and, in general, desire, and in addition to these, pleasure and pain" (436^a8–10). Since the *De Anima* has already touched upon some of them, it seems to be presupposed that there is a way of dealing with them that is appropriate for its project, even though it studies the soul as such and does not consider, for example, sense perception as common to body and soul.

This is most probably not intended to say that the *De Anima* is oblivious to the fact that each of the capacities it distinguishes (with the well-known possible exception of the understanding) requires a suitable bodily part and that the soul as a whole requires a suitable body that is potentially alive. Even in this treatise Aristotle refers to perceptual organs and sometimes even to their material constitution (especially because the constitution is important for an organ's receptivity of certain perceptible qualities). It is, however, less interested in other questions that might characterize a study of activities that are common to body and soul, for example, anatomical and physiological details, locations within the body, and extraordinary and pathological phenomena such as fever, the effects of alcohol, melancholy, or bodily conditions due to very young or very old age.

In order to motivate a complementary study of activities that are common to body and soul, it is not enough to study activities of the soul that are manifested in some bodily parts. It requires a stronger sense of "common to body and soul," perhaps one that amounts to saying that these activities are studied insofar as they are common to body and soul. This, again, might mean that one has to deal in detail with bodily processes or the bodily environment as well as with accounts of how psychic phenomena such as dreams, memory, recollection, and so on come about due to a collaboration of body and soul—for example, through appearances, on the one hand, and the way they are stored in specific bodily regions and processed or impaired by phenomena such as rising heat, side effects of digestion, and so forth, on the other. When, for example,

in *On Memory* 2, Aristotle refers to indications that recollection is "something bodily" (453ª14), he is no longer interested in the by now trivial fact that the affections of the soul do not come about without the body. Rather, he is eager to show how the model of coordinated sequences of bodily movements that was presupposed in his account of recollection finds support in certain pathological bodily circumstances that obstruct these sequences. The interest he displays in such questions is typical of the *Parva Naturalia*, while their absence from the *De Anima* is telling with regard to the division of labor within Aristotle's study of the functions of the soul.

Inasmuch as the *De Anima* confines itself to the study of the soul and its capacities as such, it leaves a blank space for the complementary study that aims to enrich the causal explanatory picture by focusing more squarely on the somatic preconditions and material causes involved in various affections and activities of living beings. The treatises in the *Parva Naturalia* (at least, in the first section) exemplify this sort of complementarity quite clearly. Apart from sense perception, memory, and the various types of desire, which in *De Sensu* 1 are referred to as "the most important" activities common to body and soul, Aristotle also mentions the study of waking and sleeping, youth and old age, inhalation and exhalation, life and death, which roughly correspond to the second section of the *Parva Naturalia*, which involve only the nutritive soul, while the functions treated in the first section mostly involve the perceptual soul.

It remains to add that none of the treatises traditionally ascribed to the *Parva Naturalia* deals with certain psychic phenomena that were announced in *De Sensu* 1, namely, "spirit, appetite, and, in general, desire, and in addition to these, pleasure and pain." Yet desire plays a crucial role in Aristotle's account of animal movement or spatial movement. It is through an animal's desire for some object that all animals move themselves. This account is developed at length in *De Motu Animalium*, which discusses it precisely as an activity that is common to body and soul, in that it treats not only the psychic capacities that are involved in animals' self-movement, but also the bodily instrument by which self-propelled spatial movement is accomplished. The natural place for this treatise within the system of Aristotelian works would thus be at the end of the first section of the *Parva Naturalia*, since without it the project announced in *De Sensu* 1 would remain incomplete.

3.5. Transition: The Studies of the Soul and of Animals as Intertwined

The treatment of the soul as a starting-point of living beings invites all sorts of studies that make use of this starting-point in the domain of living beings. In this respect, the *De Anima* might be considered a foundational text for the studies of all living beings, both animals and plants. Indeed, there are passages that present the *De Anima* and the *Parva Naturalia*, on the one hand, and Aristotle's zoological works, on the other, as closely intertwined. At the end of *De Motu Animalium*, which, as we saw, should be attached to the project of the *Parva Naturalia*, Aristotle says:

> As regards the parts of each animal, as regards soul, and further as regards perception, sleep, memory, and the common movement, we have given the causes; it remains to speak about generation. (704^{a}3–704^{b}3)

What he is referring to is, first, the zoological work *On the Parts of Animals*, second, to the *De Anima*, third, to the first section of the *Parva Naturalia* together with *De Motu Animalium*, and finally to the zoological work *On the Generation of Animals*. This is a sequence of works that either belong to the study of the soul and the functions common to body and soul or to the zoological works more narrowly conceived.

What is genuinely unclear, though, is the nature of the sequence stated: Is Aristotle speaking of the chronology of these works, that is, about what he wrote first and what afterward and what still needs to be written? If so, why would that matter to his readers? Or is the sequence rather referring to an envisaged order of study? For example, after dealing with the parts of animals, should one deal with the soul and the functions common to body and soul, and only then with the generation or reproduction of animals? Either way, the intertwining of the study of soul and the zoological works firmly accommodates the study of soul within the study of nature and living beings generally speaking (or, at least, the study of all parts of soul except the understanding, which is said to be a different sort of soul); at the same time it makes clear that, as Aristotle points out in *On the Parts of Animals* 1, the philosopher of nature who wants to inquire into animals, has to consider the soul or, at least, the relevant parts of it (641^{a}18–^{b}10).

3.6. The Zoological Works

As the grand plan shows, Aristotle's philosophy of nature would be incomplete without biology, the study of animals and plants (even though no Aristotelian work on plants has come down to us). And this study is, above all, empirically oriented, but it also draws on the theory of the soul and its functions from the *De Anima* and the *Parva Naturalia*, the four-causes theory from the *Physics*, the hylomorphism of the *Physics* and the *Metaphysics*, and, of course, the scientific methodology as presented in the *Analytics*.

In a famous passage, Aristotle promotes the study of animals (as against those who confine themselves to the study of everlasting and divine beings) by pointing out that we know so much more about animals than we know about remote celestial beings, just because we live among them (*PA* 644^{b}24–29). This empirical foundation of Aristotle's zoology is impressively documented by the longest of all Aristotelian works, *On the History of Animals*, which provides a collection of facts or observations about the parts of animals (that is, their anatomy; roughly *HA* 1–4), their reproduction and the reproductive organs (*HA* 5–7), and their manners of life together with their characters (*HA* 8–9).

The work is said to deal with the differences between animals "in accord with their lives, actions, characters, and parts" (*HA* 487^{a}11–12). In the course of it, Aristotle describes hundreds of species of animals and derives many of his anatomic observations

from dissections of animal bodies. Many details he seems to owe to the reports of experts, such as fishermen, animal breeders, beekeepers, shepherds, herdsmen, sponge divers, bird-catchers, and hunters. He also describes animals that were almost certainly exotic to him—for example, crocodiles, hippopotami, elephants, and camels—thus apparently relying on travel reports. He starts with the examination of human beings (*HA* 491^{a}19–23, *PA* 656^{a}7–10), since human anatomy is more familiar to the human researcher, and thus *On the History of Animals* also includes many details about human anatomy, representing the state of medical craft of Aristotle's time.

Merely saying, though, that *On the History of Animals* is a collection of observations may conceal the fact that it also represents one of the greatest achievements of Aristotle's biology. For in order to organize all the material he presents here, he has to introduce his taxonomy of animals, which already prefigures in many important respects Linnaeus' famous *Animal Kingdom* (*Regnum Animale*). Aristotle distinguishes between blooded and bloodless animals (roughly corresponding to the modern distinction between the vertebrates and invertebrates) and subdivides the former into five "highest kinds" and the latter into four. Among the blooded animals there are birds, fish, cetaceans, the egg-laying four-footed animals, human beings together with live-bearing four-footed animals, while the four kinds of bloodless animals are hard-shelled animals or shellfish, soft-shelled animals (crayfish, crab, lobster, etc.), soft-bodied animals, and insects (see *HA* 490^{b}7–15 with 505^{b}25–32).

The differences and resemblances between different kinds and forms (traditionally, "genera and species") of animals pose a general problem for the organization of zoological research. Is the science of animals supposed to deal with each kind of them separately or should it deal with affections that different forms have in common, since, for example, all animals sleep, breath, grow, decay, and pass away? If zoologists follow the first path, which is suggested by the distinctness of animal species, they would have to say the same things again and again—for example, when discussing sleep in dogs, cats, hedgehogs, rabbits, and so on. This problem is dealt with in *On the Parts of Animals* 1, which serves as a general methodological introduction into the study of animals (in addition to the methodology provided by the *Posterior Analytics* and the discussion of starting-points and causes in the *Physics*, as the study of animals faces peculiar challenges).

Aristotle points out that the parts of two different kinds of animals might differ only in degree or might be different in shape or configuration, while being merely analogous in those respects. For example, the differences between different species of birds are a matter of "the more and the less"—some birds have long feathers, others short ones, while fishes differ from birds by analogy "for what is feather in the one is scale in the other" (*PA* 644^{a}21–22). Differences between animals might thus be more or less significant: they are insignificant when they only concern different sizes or the softness/hardness and smoothness/roughness of their parts. Aristotle therefore suggests that one might treat common affections or parts of different animals together, as long as they have a common nature or else contain closely allied parts or affections. And this

is pretty much what he practices throughout his zoological work. He is happy to discuss the bodily parts, the reproduction, or the characteristic activities of all related animals or animals within one kind together, but he is prepared to give different accounts, whenever the differences exceed the less significant variations mentioned above.

A foundational principle running through Aristotle's zoological work as a whole is that knowledge and understanding have to proceed from knowing *that* (for example, that a thusly shaped organ belongs to animals of a certain kind) to knowing *why* (for example, because this particular kind of animal has a certain essence or nature or because animals of this kind need an organ shaped in this way for this or that purpose). Methodologically speaking, this means that research has to start with the collection of facts and then proceed to the explanations (which, according to the theory of the *Posterior Analytics*, can ultimately be presented as demonstrations): "first one must grasp the things that appear to be so about each kind, then state their causes, and then speak about their coming to be" (*PA* 640^{a}14–15; also *APr.* 46^{a}17–27).

In the case of zoology, the fact-collecting and the explanatory phases of inquiry typically appear in different treatises: The collection of facts about animal parts (organized in accord with the above-mentioned taxonomy and principles) in *On the History of Animals* 1–4 finds its explanatory counterparts in *On the Parts of Animals* 2–4, while the collection of observations about the reproduction of animals in *On the History of Animals* 5–7 corresponds to the explanatory treatise *On the Generation of Animals*. The collection of facts about animal modes of life and character in *On the History of Animals* 8–9, however, is not matched by an explanatory treatise.

In addition to *On the Parts of Animals* there is a short treatise *On the Progression of Animals*, in which Aristotle focuses on the parts of animals that are required for the different sorts of progression, such as walking, swimming, and flying, and discusses why these parts are shaped and arranged as they are. Although the titles of this treatise and of *De Motu Animalium—On the Movement of Animals*—could easily be confused, the two books have quite different agendas. The former is concerned with differently shaped extremities possessed by different kinds of animals and required for different types of progression, while the latter is interested in the common account of animal movement and in self-movement as a function that is common to body and soul.

What does an explanation in the explanatory part of Aristotle's zoology look like? With regard to what Aristotle calls the "parts" of animals (which include their overall external shape, extremities, inner, uniform and non-uniform parts, organs, tissues, body fluids, etc.) the explanation often takes the form of showing how the "part" contributes to one of the life functions, such as perception, breathing, self-nourishing, reproduction, and protection. Starting from the oft-repeated heuristic principle that "nature does nothing pointlessly," Aristotle also tries to explain why particular parts of animals have a certain size, shape, or position within the body. For example, why do animals have the part called the "epiglottis"? In order to protect the windpipe. Why does the windpipe need to be protected? Because it is located in front of the esophagus, so that pieces of food can get into the windpipe. Why, then, is the windpipe in front of

the esophagus? Because it must be connected with lungs, which are located in the front, if it is to enable breathing. Or, to take another example, why are the feet of some birds webbed, while the feet of other birds are unwebbed, but their legs are remarkably long? Because the first kind of birds live in water and need the webbed feet for swimming, while the latter birds, say marsh birds, live in the marsh and need the long legs because of the unstable ground. Therefore, nature has allocated, as it were, the available matter to different parts of the body.

Here is another telling example of so-called final or teleological explanation in *On the Parts of Animals*. Why is it that all living human beings have an upright posture? Explanation: by their nature humans have the capacity to think. Even though thinking has no proper organ (as Aristotle thinks), thinking makes use of the so-called common perceptual capacity, which is located in the region close to the heart. Excessive weight pressing on the region close to the heart impairs the capacity's activity. In animals, such as four-footed ones, whose body is horizontally oriented, much weight presses upon the heart. Human beings' thought, however, requires a body in which it is not the case that much weight presses upon the heart, hence they have an upright posture.

Once this explanation has been established, Aristotle can rely on the erect posture of human beings in further explanations of additional features of the human body. Why do human beings have fleshy buttocks and thighs? Because the weight in the lower region of the body makes it easier for them to maintain an upright posture. Why do they have arms and hands? Because, due to their upright posture, they do not need front legs, so that nature could assign a different function and shape to their upper extremities.

In his presumably final work on zoology, *On the Generation of Animals*, Aristotle discusses the reproduction of animals (both sexual and what he considers "spontaneous" generation), the development of the embryo until birth, and to some extent, the development of the animal after birth. This treatise includes numerous observations (building on what he already mentioned in *On the History of Animals* 5–7), but it is particularly noteworthy how much this work is embedded into Aristotle's *Metaphysics*. In the latter work, Aristotle connects his theory of perishable substance with assumptions about animal generation, and *On the Generation of Animals* appears to be where he substantiates these claims.

At the beginning of *On the Generation of Animals* 1 (715^{a}11–14), Aristotle emphasizes the importance of the moving cause, suggesting that investigating this cause is almost the same as investigating the generation of animals. This should be understood in the context of *On the Parts of Animals*, where he explains the particular parts of animals with a view to their essence and purpose. Having established these points, he then explores how the various parts come into being, one by one. In sexual reproduction, this process involves animals with differentiated sexes. The male is identified as the moving cause of an offspring that belongs to the same form. His semen acts on the material provided by the mother (the menses) through inherent movement, seemingly transmitting

the substantial form belonging to the parents' shared form. Meanwhile, the body of the male's semen evaporates and does not become part of the embryo.

The information required for the heredity of individual characteristics is also stored in the mother's menses. According to one interpretation, this can be seen as a sort of two-semen theory, with two functionally differentiated seminal products. But Aristotle strongly disagrees with theories that attribute the same function to male and female semen, relying on the functional differentiation of form and matter. He also objects to pangenesis theories, which suggest that semen includes small-scale models of all parts of the parents' bodies. Instead, the father's semen initiates the generation of one primary organ, the heart, which then begins to control the subsequent process of generating other parts in a sequence Aristotle considers necessary. This sequence is determined by the particular organs' contributions to the functions of the nutritive and later the sensitive soul.

3.7. Theoretical Wisdom or Primary Philosophy

Aristotle's *Metaphysics* is one of the most influential works of ancient philosophy. It has shaped the concept and philosophical discipline of metaphysics from antiquity down to the present and its "theological" part has been adopted, in one way or another, by theologians of all Abrahamic religions. Aristotle thought that what he was doing in his *Metaphysics* is the supreme part and ultimate goal of all philosophy. And although there was no established term for this philosophical discipline prior to this work, Aristotle goes out of his way to show that all previous philosophers ultimately attempted to give answers to the question that his *Metaphysics* is meant to answer, namely, the question: What are the primary starting-points and causes of everything? At the beginning of the work Aristotle announces the project under the traditional term of *sophia* ("theoretical wisdom"), since we expect the wise person to know, as it were, everything, especially the most difficult things, things that admit of the most precise knowledge, and things people want to know for their own sake and not for any other purpose.

A bit later, when he tries to sketch a proper science that deals with these subjects, he speaks of the science "we are seeking" ($982^{a}4$), thus indicating the groundbreaking character of his project. Later on, he keeps speaking of "primary philosophy," which is also the formula he uses when he adds cross-references to the *Metaphysics* in other works. The term *meta ta phusika*, as we saw, is not used in the extant works by Aristotle and is thus probably the invention of ancient editors. It may refer to the place of the *Metaphysics* in the edition of the Aristotelian oeuvre or it may refer to an intended ideal order of study, in which the subject of the *Metaphysics* should be approached only after completing the study of nature.

That Aristotle sees the project of the *Metaphysics* in continuity with what previous philosophers were after does not mean, to be sure, that he settles for any of the previous theories. On the contrary, major parts of the *Metaphysics* are dedicated to a criticism of his predecessors and competitors (which makes it, as should be noted in passing,

an invaluable source for doxography, the collection of philosophical doctrines). He usually presents himself as opposing two different camps. One of these comprises the philosophers of nature who took the starting-points of nature to be the starting-points of all reality. Some of them did not even correctly identify the starting-points of the changeable world, because they seemed content to make use of one type of cause alone. At any rate, none of them had a proper understanding of formal (linked up with the definitional method that Aristotle accepts from the Socratic-Platonic tradition) and final causes.

On the other side are the Pythagoreans and Plato and the members of his Academy, who do have a grasp of forms and formal causes but, to put it in a nutshell, became fixated on numbers, separated eternal Forms (or a combination of both), and accounts of primary starting-points that are modeled after such entities (most of Books 13 and 14 are dedicated to the refutation of this latter sort of theory). On the whole, Aristotle thinks that these more abstract or metaphysically demanding approaches cannot adequately serve as starting-points and causes for physical substances. In fact, his approach is in one way closer to that of the first camp: he imports into the *Metaphysics* his theory of the four causes from the *Physics* and draws heavily on the paired notions of matter and form, which are first derived in the analysis of the starting-points of change and generation of natural beings. If there were no substances beyond the natural ones, the philosophers of nature would be right, and physics would turn into primary philosophy (*Met.* 1026^{a}27–32). Aristotle insists, however, the changeable world is not everything there is and, hence, the search for the truly primary starting-points must go on.

The *Metaphysics*, as it has come down to us, comprises fourteen books. All of them are clearly related to the core project of what Aristotle takes to be primary philosophy, but there have always been worries about the coherence and unity of the work and about whether its composition reflects decisions made by the early ancient editors (see Section 2). Apart from the fact that the different books included in the *Metaphysics* seem to approach the task of identifying the primary starting-points and causes from quite different angles, there are some manifest editorial problems:

- Book 11 consists solely of excerpts from the *Physics* and from Books 3, 4, and 5 of the *Metaphysics* itself.
- Books 1 and 2 present two competing introductions. And even though Book 1 includes the more substantial and more pertinent introduction, the Arabic commentators on Aristotle who only knew parts of it were able to make good sense of the *Metaphysics* as a whole, relying on the assumption that Book 2 represents the true introduction to this work.
- Parts of Book 1 are repeated in Book 13.
- Book 12, which one might expect to contain the work's main answer to the question posed, does not seem to be well-connected with certain other books; for example, it does not seem to include any back- or forward-references, and in its first half (12.1–5) it deals with perceptible substances, which have also been the subject of Books 7 and 8.

- Many scholars are also worried about Book 5, which presents a sort of lexicon of thirty key terms which are "said in many ways." All these terms are somehow pertinent (some more than others), but why do we need such a lexicon at all and why at this particular place?

Owing to these and related problems, some scholars have opposed any attempt to read the *Metaphysics* in its transmitted form as a coherent work and focused instead on particular books or particular groups of books, such as Books 7–9, which some regard as a more or less self-contained project about perceptible substance.

On the other hand, there are also indications of an intended coherence of the work. For example, Book 3 presents fifteen puzzles that the outlined science of primary starting-points and causes has to face. And throughout the *Metaphysics* one can find back-references to these initial puzzles as well as apparent solutions to them, sometimes explicitly presented as such. Also, early on in the *Metaphysics* Aristotle states that "something is said to *be* in many ways." In several books we find back-references to this statement, and in two or three instances the list of different meanings of "being" is even used as a sort of guideline for what has to be accomplished within this work.

Another common thread is the notion of substance. Some beings are said to be beings because they are substances, others are said to be beings because they are dependent on or suitably related to substances. References to substances can be found throughout the *Metaphysics*, and Books 7, 8, and 12 are explicitly dedicated to the treatment of substances. Given that the notion of substance captures in one way or the other the idea of ontological priority or independence, they seem to be quite pertinent to the project of the *Metaphysics* for, whatever the primary starting-points and causes look like, it is hard to think of them as dependent beings (for then they would depend on other, independent starting-points with a better claim to being primary starting-points and causes).

How the loose ends of the different books of the *Metaphysics* should be tied together is one of the most controversial questions in Aristotle scholarship. Here are some of the signposts that interpreters of the *Metaphysics* have to deal with. After Book 1 formulates the goal of finding the primary starting-points and causes and makes clear that these starting-points must be sought in terms of the four types of causes known from the *Physics*, and after the puzzles of Book 3 provide a sort of checklist of problems to be solved by the new, sought-after science, Book 4 makes a fresh start by saying that this new science will be an inquiry into "being qua being," a concept that plays an important role also in Book 6's specification of various theoretical disciplines and various broad inquiries within primary philosophy, most notably, the division of being according to the categories.

Scholars have sometimes thought that Aristotle thereby leaves behind the project of searching for the primary starting-points and causes. However, already in 4.1 he makes clear that the new science should seek the starting-points and causes not of being qua changeable or anything like that, but of being qua being: "That is why it is of being qua being that we must grasp the primary causes" (1003^a31–32). In 4.2 Aristotle

immediately appeals to the many ways in which things are said to *be*, a phenomenon that, in principle, could jeopardize the unity of an inquiry into being qua being. He makes clear, however, that the various ways are unified in that they are all related to one single type of thing, which is substance. He also outlines how an inquiry into being should deal with the affections of being (for example, one or sameness) and their contraries (for example, distinctness).

From 4.3 on, the discussion turns to certain axioms that are said to be most stable and to hold true of all beings, such as the principle of non-contradiction. These axioms, it turns out, are indeed starting-points that primary philosophy must deal with (which seems to be a first result), but they are starting-points of proof (only), not of substance, which leaves it to the later part of the study to identify primary starting-points that are starting-points of substance.

It is Book 6 that finally introduces the notion of primary philosophy by opposing it to other parts of theoretical philosophy. Primary philosophy is said to deal with unmoved and separable things, and in this context it is also equated to theology, the science of divine beings. This move has puzzled scholars because it is no longer clear whether the project carried out in the *Metaphysics* is meant to be about all beings (a universal science of being qua being), or about a certain elevated region of being, the separate, unmoved (and divine?) being. Or can both aspects be reconciled by assuming that the science is about separate, unmoved beings that are (among) the primary starting-points and causes of all beings, so that the study of these beings would be universal by being primary (1026^{a}30–31), that is, by being concerned with the starting-points of everything?

In light of the prominence of substance within a study of being qua being and also in light of the claim that everything else is dependent on substance, it is no surprise that Aristotle dedicates a detailed discussion to substance. Books 7 and 8 give important insights into the notion of substance in general, but are primarily concerned with material, changeable, perishable substances. Substances are the substrates or bearers of non-substantial affections; in the case of material substances matter is also a sort of substrate in that it underlies the determinacy that defines what each thing is. Relatedly, Books 7 and 8 give pride of place to what Aristotle calls *to ti ên einai*, the essence of a thing. It is this essence that makes each particular thing the kind of thing it is. In this sense, essence is said to be the "cause of being" of each thing. Aristotle argues that for material, perceptible substances, a thing's form is its essence. Therefore forms, as essences, are causes and starting-points of material substance (which, again, is a positive result).

However, they are not starting-points and causes of everything, but only of perceptible substances, and they only occur in the suitable sort of matter. Matter and form relate to each other as potentiality to actuality: the matter of a house is this house-in-potentiality, while it is the form (imposed by an architect, that is, an efficient cause) that turns the potential house into an actual one. Thus, the conceptual pair of potentiality and actuality becomes more and more important in the discussion of substance, which

might be the reason why Book 9.1–9 is entirely dedicated to being-in-potentiality and being-in-actuality (and includes a remarkable series of arguments for the priority of being-in-actuality).

In the end all eyes are focused on Book 12, which is supposed not only to come up with the highest starting-points, but also to tie together the loose ends of the previous discussions. Since it fails, to some extent, to meet the second expectation, scholars have wondered whether it really contains the discussion that Aristotle has announced throughout the *Metaphysics* or whether it is an independently drafted treatise used to provide, for example, a discussion of immaterial substance, otherwise notably absent from the *Metaphysics*. However that may be, it clearly distinguishes, first, perceptible and perishable substance, second, perceptible and imperishable substance (like the celestial bodies that Aristotle takes to be everlasting), and, third, non-perceptible and imperishable substance. The latter exists without matter and, hence, in pure actuality; in fact, Aristotle argues that such a purely actual substance must exist in order to guarantee the eternal, uninterrupted movement of the world as a whole. It therefore serves as an immovable mover, the existence of which has also been proved in *Physics* 8.

"This, therefore, is the sort of starting-point on which the heaven and nature depend" (*Met.* 1072^{b}13–14), Aristotle writes, and this seems to be his way of saying that this is (one of) the primary starting-point(s) he was looking for. It moves the world in the way that objects of desire or love move something else, that is, without itself being moved. In this way the immovable mover moves the outermost celestial sphere (eternally moving in a circle), while this outermost sphere or "primary heaven" is responsible for moving the adjacent celestial spheres. For Aristotle, such an immaterial substance, one that by its essence is actual being, can only be thought of as an everlasting understanding, which is divine and spends the best, most joyful life by thinking without interruption (this is probably why theorizing about this substance might also be described as "theological").

Aristotle also assumes a kinship between this divine understanding and the one found in the human soul that does not have a bodily organ (as Aristotle notoriously assumes). Human understanding can thus be seen as a divine element in human beings. However, while divine understanding, the immovable mover, never tires of thinking of itself, we human beings, being corporeal and anchored in social communities, can activate our thinking (and thereby enjoy the sublime pleasure of intellectual activity) only for a short period of time. This is also part of the reason why Aristotle holds the theoretical activity and, in particular, the part of philosophy that contemplates the primary starting-points, in such high esteem.

3.8. The Science of Human Affairs: Ethics and Politics

Aristotle's subdivision of sciences relies crucially on the distinction between things whose starting-points cannot be otherwise (not in the sense that these things cannot undergo change, but in the sense that they are subject to by-necessity-statements) and subjects that typically can be otherwise. With regard to the former subjects, we can

contemplate or understand them, while the latter things can be altered, attained, or produced by human agents and craftsmen (see *EE* 1214^{a}8–14). It is this latter group of things with which the practical and productive parts of Aristotle's philosophy are concerned. In *Nicomachean Ethics* 6 he even maps this distinction onto the architecture of the rational, reason-possessing part of the soul, insisting that there are two parts of it corresponding to subjects that can be otherwise and those that cannot (1139^{a}6–12). Whether one deals with subjects of the former or subjects of the latter type makes all the difference regarding the exactness and status of statements we can make about them.

The distinctively practical science, which comprises ethics and political philosophy, is more narrowly defined by its occupation with human action. Though Aristotle sometimes refers to both the moral and political fields taken together as the "philosophy of human affairs" (*NE* 1181^{b}15), he more frequently subsumes them under the heading of "politics," which is misleading for the modern reader, as it not only comprises Aristotle's political philosophy, but also what we call "ethics" or "moral philosophy." Aristotle's moral philosophy (as developed in the *Eudemian* and *Nicomachean Ethics*) is one part of what he calls "politics," the other part being his political philosophy in the narrow sense (as presented in his *Politics*), which deals with the nature of the city or *polis*, the citizen, and, above all, the comparison of political constitutions.

For Aristotle, indeed, the adjective "political" just means that something or someone is related to the *polis*, so that the difference between moral philosophy on the one hand and political philosophy on the other seems to boil down to the difference between treating human happiness and its attainment from the perspective of individuals and treating it from the perspective of the entire *polis* (*NE* 1094^{a}26–^{b}10), that is, with a view to political conditions that either facilitate or impede the individual attainment of happiness.

Aristotle assumes that a city supports its citizens' quest for happiness by good legislation, above all. This is because human beings acquire their stable traits of character in accord with how they act—good character traits from good actions and bad traits from bad actions—and because good laws have an important role to play in making people act well. This is why Aristotle in the *Eudemian* and *Nicomachean Ethics* keeps addressing or referring to prospective legislators, for whom he takes his discussion of moral philosophical questions to be most pertinent, because it is they in particular who will be responsible for the legislation that helps people achieve happiness.

There is the notorious problem, as we saw, of why there are these two treatises and why the three common books (*EE* 4–6 = *NE* 5–7) have been transmitted as parts of both of them. By and large, the agenda of both treatises is similar: apart from the common books, each includes a discussion of the supreme good and happiness, the definition of virtue of character, particular virtues of character, pleasure (in *EE* 6, *NE* 7 + 10.1–5), and friendship (*EE* 7, *NE* 8–9). Still, there are also not insignificant philosophical differences between them—for example, *EE* 8.3 identifies the contemplation of god as the supreme end of human life, while *NE* 10.7–8 speaks of the contemplative

life more generally and also acknowledges the life in the city as appropriate for human beings.

What, then, is the relation between these two—to some extent competing—works on ethics? Can one of them be regarded as superseding the other—for example, one being an early attempt, the other being better considered, or one representing the original insight, the other being more mature and less uncompromising? Many scholars lean toward thinking that the *Eudemian Ethics* is the earlier work, but no general consensus has been reached, in particular about the common books. One problem that commentators must confront in answering these questions is that, in terms of reception, the *Nicomachean Ethics* has surpassed the other to such a great extent that it is difficult not to read the *Eudemian Ethics* through its lens.

Apart from the co-existence of two ethical works, the crucial question for the unity of the practical division of Aristotle's philosophy concerns the role of the *Politics*. As already mentioned, Aristotle seems to say that the former treatises deal with individual attainment of happiness, while the latter deals with collective happiness in the city and the legal-constitutional conditions that facilitate its acquisition. And the *Politics* has a lot to say, indeed, about the comparative value of different constitutions, the search for the best constitution, and the virtues of citizens—topics that suggest a kinship between political philosophy and ethics. At the same time, the agenda of the *Politics* goes clearly beyond this narrow ethical, virtue-related agenda, in that Aristotle is also interested in non-ideal states and constitutions, namely, real cities that, due to incidental conditions such as poverty, civil unrest, the character of the inhabitants, and so on, do not match up to the ideal of educating their citizens in virtue and are not governed by virtuous leaders. In particular, the so-called empirical books (4–6) deal with a wide range of real constitutions which can do better or worse—for example, with regard to political stability, the avoidance of political coups, and the integration of different social groups. All these factors, Aristotle assumes, can make a difference to life in these cities, even though they need not directly pertain to the virtues of the citizenry.

Methodologically speaking, Aristotle continually emphasizes that the epistemic status of moral philosophy, broadly conceived, is quite distinctive. While in strictly theoretical philosophy and science an Aristotelian philosopher often aims at demonstrating that if a certain individual object belongs to a certain universal kind, it must have certain intrinsic coincidents by necessity, it would be inappropriate to expect such results in the domain of moral philosophy. For even if it is highly plausible to say that certain things (for example—health, wealth, beauty, good fortune) are good and beneficial for most people, the moral philosopher is not in a position to deduce that they are good and beneficial for everyone, since in some, perhaps only a few, cases, those things commonly held to be good may turn out to be harmful. Aristotle draws the unambiguous conclusion that one cannot expect ethical statements to have the same exactness as, for example, mathematical ones. In ethics, he says, one deals with what happens "for the most part" and must be content to give an "outline" of what it means to have a happy life, and so on. The clear message is that approaching moral philosophy

with the standards of strictly theoretical philosophy or science in mind would inevitably lead to mistakes.

This seems reasonable, as it stands. But what are the alternatives? Yielding the floor to those who make ethics a matter of mere conventions and subjective preferences? Clearly, this cannot be Aristotle's point of view, for it is the core project of his moral philosophy to derive, at least, a general outline of forms of life that are suitable for attaining happiness. Obviously, these questions have been taken up in exciting philosophical and exegetical debates, which may have consequences not only for the understanding of Aristotle, but also for the way one thinks of moral philosophizing quite generally. Since Aristotle seems to be saying that ethics is not like an ordinary science, not allowing of scientific demonstrations, some scholars have suggested that what he is doing in his ethico-political treatises is more like dialectic, perhaps drawing on, and refining, what people think about happiness. Others have tied these remarks about precision to Aristotle's intellectual virtue of practical wisdom, which they understand as an experience-based ability to make good decisions in particular affairs with a view to what matters for life as a whole, but cannot be codified as a full-fledged Aristotelian science. Still others have argued that Aristotle did not intend by his remarks about the status of ethical questions to dismiss the scientific model of the theoretical sciences (sketched in the *Posterior Analytics*) entirely, but only to ensure more flexibility vis-à-vis the perhaps overly strict demands of theoretical inquiry. On this reading the study of human agency and human happiness would use some of the same methods that Aristotle uses elsewhere (for example, the method of defining the core concepts, of dealing with puzzles, identifying certain starting-points, etc.) without attempting, though, to give demonstrations of what is good or bad in a particular case (which is a matter for practical wisdom, not science).

3.9. From Ethics to Moral Psychology

In broad outline, it is clear that, according to Aristotle, the happy life for human beings flows from and consists in steady or repeated activities in accord with the virtues or excellences of the parts of the soul that are peculiar to human beings—these are, first, the part that possesses reason (the excellences of which are the so-called virtues of thought, such as practical wisdom and theoretical wisdom) and, second, the part that is not itself rational but is able to obey to reason (the excellences of which are the so-called virtues of character).

Most of the particular virtues that Aristotle lists, for example, courage, temperance, justice, and generosity, are clearly acknowledged by Greek popular morality of his time. But his ambition is to show that they can actually be seen as genuine virtues of the human soul, that is, as the best states of those parts of the soul that, according to human nature, are peculiar to human beings and thus contribute to their well-being and happiness. The non-rational part of the human soul is in its best state when people are disposed by their character traits to do the right things, to have the appropriate feelings,

and to take pleasure in doing the right things or to do them easily. This is important to emphasize because it demonstrates to what extent Aristotle's ethics is entangled with his moral psychology.

Aristotle's deep and profound interest in questions of moral psychology—questions concerning feelings, desires, the experience of pleasure and pain, deliberation, decision making, character traits, and habituation—is a common thread that can be found in many Aristotelian treatises, even though there is not one single treatise that is dedicated to it. True, the ethical treatises themselves have a lot to say about moral psychology, especially when it comes to character virtues, decision making, and habituation, but additional pieces of Aristotle's moral psychology must be gathered from different projects. The *Poetics* and the *Rhetoric*, in particular, deal quite extensively with questions of character and feelings. *Rhetoric* 2.2–11 is the most elaborate discussion of different types of human feelings available at the time. In the two last books of *On the History of Animals*, Aristotle speaks of character traits and feelings that one finds in non-human animals. The *De Anima* famously uses feelings as paradigm cases for psycho-somatic affections, for one cannot have a feeling without also undergoing somatic alternations. Likewise, *De Motu* accounts for both the psychological and the somatic conditions that, taken together, are sufficient for the self-motion of animals.

3.10. The Two Remaining Projects: Rhetoric and Poetics

The *Rhetoric* and the *Poetics*, both major and extensively received works, do not seem to easily fit into Aristotle's research program of either theoretical or practical philosophy. The widespread puzzlement about their place within his system and oeuvre is indicated, for example, by the fact that they were not even included in the first printed edition of his works and that the medieval Aristotle commentators in the Islamic world ended up assigning them to the *Organon*. Even though both works have a significant terminological overlap with Aristotle's moral and political philosophy, especially with its moral psychological part (dealing with feelings and character), they are not part of the same project. Both deal with phenomena that are deeply rooted in the Athenian cultural life of Aristotle's time, namely, epic poetry and theater (the *Poetics*) and oratory (the *Rhetoric*). While these phenomena might be thought to have a harmful impact on the public (as Plato forcefully argued), Aristotle shows that neither of them needs to be considered pernicious, as long as they are understood and conducted in an appropriate way. The feelings elicited by tragedy, for example, far from spoiling the spectators, may even have an innocent purgative or relieving effect. Speeches composed in accord with Aristotle's rhetorical craft may enhance a jury's or assembly's judgment rather than corrupt or distract them. Still, neither the *Poetics* nor the *Rhetoric* directly contributes to the attainment of virtue in the way that the ethical and political treatises do.

The most common solution, therefore, is to couple the *Rhetoric* and the *Poetics* as the two representatives of productive, rather than practical or action-focused, crafts or sciences. But what sort of products exactly are these two works aiming at? The *Poetics*

analyzes the ingredients of good tragedies and good epic poetry. There is no doubt that a poet could benefit from reading it. Does this mean that the *Poetics* has tragedies and epic poems as its defining products in the way that medicine has health as its product? Similarly, the *Rhetoric* deals with what is potentially persuasive (in public speeches). There is no doubt that an orator could benefit from reading this work. Does this mean that speeches are the product of the craft of rhetoric just as shoes are the product of the craft of shoemaking? Or perhaps is it rather persuasion on the hearer's side that is the product at which the craft of rhetoric ultimately aims? Since tragedy is partly defined by the emotional effect on the spectator, should one argue, along the same lines, that this peculiar effect (purgation of tragic feelings) is the ultimate product of the craft of tragic poetry?

What seems to be unfortunate about the label of "productive" sciences or "crafts" is the impression that the respective works would directly instruct the readers in how to bring about the product in question, but this is not exactly what we find in these two works. If Aristotle's *Rhetoric* is meant to help to arrange or to deliver better speeches, it is rather by providing a better understanding of the factors contributing to persuasiveness. Accordingly, the best rhetorician is not the one who manages to convince each and every audience, but the one who is able to see the persuasive potential in any given case. Similarly, if the *Poetics* is meant to contribute to the composition of tragedies it is not by providing guidelines for poets (as in a creative writing class), but rather by getting clear about what is essential and what is rather incidental to a tragedy. For example, every tragedy consists, according to Aristotle's analysis, of six aspects: plot, character, style of speech, thought, spectacle, and melody-composition. If a tragedy is meant to bring about the tragic feelings of pity and fear together with the purgation of such feelings (which is either a pleasant relief from these rather unpleasant feelings or, as some say, a sort of purification of them), it turns out that the one aspect many people care about most, namely, spectacle, is the least important, while the plot alone should be sufficient to bring about the mentioned effect. And in order to construct the right plot, one has to understand the nature of tragic feelings and what sorts of people and actions are likely to bring them about. This is the sort of knowledge that the *Poetics* actually provides. It thus focuses on understanding the very nature of each poetic genre it deals with, and by conveying this understanding it may contribute to the production of better tragedies.

Apart from the special status that these two treatises seem to have by presenting supposedly productive crafts or methods, the *Rhetoric* and the *Poetics* are conceptionally well-connected both with each other and with the rest of the oeuvre. The core theorem of the *Rhetoric*, to begin with, says that there are mainly three factors that bring about persuasion and that can be provided by the rhetorical craft itself: rhetorical arguments, the character of the audience, and the credibility of the speaker. As for the arguments, Aristotle refers to dialectic (as the arguments of public speech have to start with premises that are accepted by the audience), while for the arousal of feelings and the presentation of character he refers to moral philosophy and its already highlighted

expertise in moral-psychological questions. The craft of rhetoric is hence an offshoot of dialectic and political science, insofar as it deals with character.

In the final book of the *Rhetoric* Aristotle turns to a slightly different aspect of the method of persuasion, namely, by looking into the style of speech we use, insofar as it makes a difference for persuasion and understanding. Style of speech again is a topic that the *Poetics* has dealt with at some length in Chapters 19–22, and this is why in the *Rhetoric* Aristotle explicitly refers to the *Poetics*' discussion of this theme. The *Poetics*' account of style again has to deploy a categorization of types of words, a distinction between simple words and sentences, and so on. This touches upon fundamental questions of Aristotle's philosophy of language, as it has been discussed in the *Organon,* above all in the first chapters of *De Interpretatione*.

CATEGORIES*

1
Homonymy, Synonymy, and Paronymy

Things are said to be homonymous when they have only the name in common but the account[1] that corresponds to the name is distinct—for example, both a human and a drawing are animals;[2] for only the name of these is common to them both, whereas the account that corresponds to the name is distinct; for if one specifies what it is for each of them to be an animal, one will give a special account to each. **1ª1** 5

Things are said to be synonymous when they have both a name in common and the account that corresponds to the name is the same—for example, both a human and an ox are animals; for each of them is called by the same name, "animal," and, moreover, the account is the same; for if one gives an account of what it is for each of these to be what it is, an animal, one will give the same account. 10

Things are said to be paronymous in case one gets its name from the other with some difference depending on derivation—for example, the grammarian gets his name from grammar, the courageous person from courage. 15

2
Said-of-a-Subject versus in-a-Subject

Among things that are said, some are said in combination, some without combination. Examples of things said in combination are "a human runs," "a human wins." Examples of things said without combination are "human," "ox," "runs," "wins."

Among the things that there are: Some are said of a subject but are not *in* any subject—for example, human is said of a subject, a particular human, but is not in any subject. Some are in a subject but are not said of any subject. (I call "in a subject" what is in something, not as a part, and cannot exist separately from what it is in.) For example, a particular bit of grammatical knowledge is in a subject, the soul, but it is not said of any subject; and a particular white is in a subject, the body, for all 20 25

* Translated by S. Marc Cohen. Text: L. Minio-Paluello, *Categoriae et Liber De Interpretatione* (Oxford, 1956). The title is a transliteration of the Greek title, *Katêgoriai*. In a legal context this word means "accusations" or "charges"; as Aristotle uses it, however, it means "predicates." The *Categories*, then, is a study of predication, i.e., saying something *of* something, as when one says of an animal that it is a horse, or of a particular horse that it is white.

1. Secluding τῆς οὐσίας ("of the substance") here and subsequently in this chapter.

2. The word *zô[i]on* can mean either an animal or a figure in a picture; the latter need not be the figure of an animal.

colors are in body, but it is not said of any subject. Some are both said of a subject
1b1 and are in a subject—for example, knowledge is in a subject, the soul, and is said of a subject, grammar. Some are neither in a subject nor said of a subject—for example,
5 a particular human or a particular horse. Nothing of this sort is either in a subject or said of a subject.

Unconditionally, things that are individual and one in number are not said of any subject, but nothing prevents some of them from being in a subject. A particular bit of grammatical knowledge is among the things in a subject.

3
Said-of-a-Subject

10 Whenever one thing is predicated of another as of a subject,[3] everything said of what is predicated will also be said of the subject—for example, human is predicated of the particular human, and animal is predicated of human; therefore, animal will also be predicated of
15 the particular human; for the particular human is both a human and an animal.

Differences between kinds that are distinct[4] and not subordinate to each other are also distinct in form—for example, differences in animal and in knowledge. For the differences in animal are, for instance, terrestrial, flying, aquatic, and two-footed, but none of these is a difference in knowledge—one sort of knowledge does not differ
20 from another by being two-footed. Yet if one kind is subordinate to another, nothing prevents their differences from being the same; for the higher kinds are predicated of those beneath them, so that all differences in what is predicated will be differences in the subject as well.

4
The Ten Categories

25 Each of the things said without any combination signifies either a substance, or how much [quantity], or of what sort [quality], or related to what [relative], or where, or when, or being arranged, or having on, or doing, or being affected. To give a general indication of what these things are, here are some examples:

Substance	human, horse
Quantity	two cubits, three cubits
Quality	white, grammatical

3. "Predicated of another as of a subject" seems to be equivalent to the semi-technical term "said of a subject" introduced at 1a20. Thus the import of this paragraph seems to be that the "said of" relation is transitive.

4. Reading ἑτέρων γενῶν.

Relative	double, half, larger	
Where	in the Lyceum, in the marketplace	**2^a1**
When	yesterday, last year	
Being arranged	lying, sitting	
Having on	wearing shoes, having armor on	
Doing	cutting, burning	
Being affected	being cut, being burned	

None of the things mentioned above, said just by itself, constitutes an affirmation, but by a combination with others of these an affirmation is produced; for it seems that every affirmation is either true or false; but none of the things said without combination—such as "human," "white," "runs," "wins"—is either true or false.[5]

5
Substance

Substance in the strictest sense, that which is primarily and most of all called "substance," is what is neither said of any subject, nor is it in any subject—for example, a particular human or a particular horse. What are called "secondary substances" are the forms that the things primarily called "substances" are instances of, both these forms themselves and the kinds of these forms—for example, the particular human is an instance of the form human, and the kind of the form is animal. So these things—for example, human and animal—are called "secondary substances."

It is evident from what has been said that both the name and the account of a thing *said of a subject* must be predicable of the subject. For example, human is said of a subject, the particular human, and so the name is predicated—for you will be predicating human of the particular human; and also the account of human will be predicated of the particular human; for the particular human is also a human. Thus, both the name and the account will be predicated of the subject.

But as regards the things that are *in* a subject, in most cases, neither the name nor the account is predicated of the subject. In some cases, however, nothing prevents the name from being predicated of the subject, but for the account it is impossible;[6] for example, white, which is in a subject, the body, is predicated of the subject—for the body is said to be white—but the account of white will never be predicated of the body.

5. *Int.* 17^a9–12 adds an important qualification.

6. Typically, it is the name of a *paronym* of what is in a subject that is predicated of the subject (1^a12–15). It is "courageous," not "courage," that is predicated of Socrates. But sometimes, the name of what is in a subject will be identical to the name of its paronym, as "white" is both the name of a color and the adjective that is predicated of what has that color in it (*Met.* 1031^b23).

All other things either are said of primary substances as of subjects or are in them as subjects. This is evident from a consideration of particular cases—for example, animal is predicated of human, and therefore of the particular human (for if it were predicated of no particular human, it would not be predicated of human at all). **2^b1** Again, color is in a body, and therefore in a particular body (for if it were not in any particular body, it would not be in a body at all). Thus, all other things either are said of primary substances as of subjects or are in them as subjects. So if there were no primary substances, it would be impossible for anything else to be.

Among secondary substances, the form is more of a substance than the kind; for it is closer to the primary substance. If one were to specify for a primary substance what it is, it would be more informative and more appropriate to specify it by giving the form than the kind—for example, in the case of a particular human, it would be more informative to give human rather than animal; for the former is more special to the particular human, while the latter is more common. And in the case of specifying a particular tree, it is more informative to specify it by giving tree than by giving plant. Further, primary substances are subjects for all other things, and therefore all other things are predicated of them or are in them, and it is for this reason that they are called "substances" most of all. But as primary substances are in relation to other things, so form is in relation to kind; for a form is a subject for its kind. And while kinds are predicated of their forms, the converse does not hold—that is, forms are not predicated of their kinds. So on the basis of these considerations too, the form is more of a substance than is the kind.

Among forms that are not themselves kinds,[7] none is more of a substance than another; for it is no more appropriate to give human in the case of a particular human than it is to give horse in the case of a particular horse. Similarly, among primary substances none is more of a substance than another; for a particular human is no more of a substance than is a particular ox.

It is reasonable that, after primary substances, forms and kinds alone among everything else should be called "secondary substances"; for they alone among things predicated make clear the primary substance. If we were to give [an account of] what a particular human is, we should properly specify it by giving the form or the kind—although we should do this more informatively by giving human than by giving animal. But to give any of the other things one would be to give something alien to it—for example, to give white or runs or anything whatsoever like that. So it is reasonable that of the other things only these are called "substances."

Further, it is because they are subjects for everything else that primary substances are in the strictest sense called "substances." But as primary substances are in relation **3^a1** to everything else, so the forms and the kinds of primary substances are in relation to all the rest; for all the rest are predicated of these. Thus, if one calls a particular

7. I.e., the so-called *infimae species*, or lowest-level forms, are divisible directly into their particular instances but not into lower-level sub-forms.

human "grammatical," it is both a human and an animal that one will be calling "grammatical"—and likewise for the rest.

Not being *in* a subject is something common to all substances. For a primary substance is neither said of a subject nor is it in a subject. And it is also quite clear that secondary substances are not in a subject either; for human is said of a subject, the particular human, but it is not in a subject; for human is not *in* the particular human. In similar fashion, animal is also said of a subject, the particular human; but animal is not in the particular human.

Further, as it regards a thing that is in a subject, although nothing prevents its name from sometimes being predicated of the subject, the account of such a thing cannot be predicated of it.[8] In the case of secondary substances, however, the account as well as the name can be predicated of the subject; for one will predicate of the particular human both the account of human and the account of animal. So no substance[9] is among the things in a subject.

This, however, is not special to substance; differences are not in a subject either; for terrestrial and two-footed are said of a subject, a human, but they are not in a subject; for neither two-footed nor terrestrial is in a human. Moreover, the account of a difference is predicated of what the difference would be said of—for example, if terrestrial is said of a human, the account of terrestrial will also be predicated of a human; for humans are terrestrial.

We should not be afraid that we might have to say that the parts of a substance are not themselves substances on the grounds that they are in a whole as in a subject; for it was said that the "things *in* a subject" are not like a part being in something.[10]

One characteristic of substances and differences is that everything called from them is so called synonymously; for every such predicate coming from them is predicated either of individuals or of forms. (While a primary substance yields no predicate—for a primary substance is not said of any subject—among secondary substances the form is predicated of the individual, and the kind is predicated of both the form and the individual. Similarly, differences are predicated of both forms and individuals.) Moreover, primary substances admit of the account both of their forms and of their kinds, and a form admits that of its kind. (For whatever is said of what is predicated will also be said of the subject.) Similarly, both forms and individuals admit of the account of their differences. But we saw[11] that synonymous things are those that have both a name in common and the same account. So all the things that are called from substances and differences are so called synonymously.

Every substance seems to signify a *this something*.[12] As far as primary substances are concerned, it is indisputable and true that each signifies a this something; for

8. $2^a29–34$.
9. Reading ἡ οὐσία.
10. $1^a24–25$.
11. $1^a6–7$.
12. I.e., a particular thing of some form or kind.

what is indicated is individual and one in number. But in the case of secondary substances, it seems from the appearance of the appellation that they too signify a this something, when one says [for instance] "human" or "animal." But it is not really so—rather, each signifies a certain sort;[13] for the subject is not one, as is a primary substance—rather, human and animal are said of many things. Yet a secondary substance does not simply signify a certain sort, as white does. White signifies nothing but a sort, whereas form and kind distinguish with respect to substance what sort it is of; for each of them signifies a certain sort of substance. (With a kind, the definition encompasses more than with a form; for saying "animal" embraces more than saying "human.")

Another characteristic of substances is that nothing is contrary to them. For what would be the contrary of a primary substance? For example, nothing is the contrary of a particular human, nor is anything the contrary of human or of animal. But this is not special to substance—it holds also of many other things, such as quantity; for nothing is the contrary of two cubits long, or of ten, or of any other such thing—unless someone says that many is the contrary of few, or large the contrary of small. But nothing is the contrary of any definite quantity.

It seems that substance does not admit of the more and the less. I do not mean that one substance is not more of a substance than another—indeed, I said[14] that it is so—rather, I mean that no substance is said to be more or less what it precisely is. For example, if this substance is a human, it will not be more or less a human, nor will this human be more or less a human than himself or than another. For one human being is not more a human being than another, as something white is whiter than another, or something beautiful is more so than another. And yet something may be said to be more or less than itself, as when a white body is said to be whiter now than before, and a hot body is called "hotter" or "less hot." But no substance is said of things in this way—for a human is not said to be more a human now than before, nor is any other thing among those that are substances. So the substance does not admit of more or less.

What seems most special to substance is that, while remaining the same and one in number, it can receive contraries. In no other case can one cite something one in number that can receive contraries. For example, a color that remains the same and is one in number will not be white and black; nor will the same action, one in number, be both bad and good; and similarly for other things that are not a substance. But a substance, while it remains the same and one in number, can receive contraries. One and the same human being, for example, comes to be pale at one time and dark at another, hot at one time and cold at another, bad at one time and good at another. This sort of thing is to be seen in no other case.

13. The word *poion* translated as "sort" is cognate with *poiotês*, the word for quality. It is used in Chapter 8 to apply exclusively to things in the category of quality, but in this passage it is used more broadly to apply to secondary substances.
14. 2^b6–22.

Someone might object by saying that statements and beliefs are also like this, for the same statement seems to be both true and false—for example, if the statement that someone is sitting is true, when the person stands, the same statement will be false. It is the same with beliefs, also. If one holds the true belief that someone is sitting, when the person stands—if one holds the same belief about him—the belief will be false. But even if we agree to this, there is still a difference in the way this happens. In the case of substances, it is because *they* undergo change that they can receive contraries; for what came to be cold from hot, or pale from dark, or bad from good, has changed (because it has altered). Similarly in other cases, each thing can receive contraries in that it undergoes a change itself. Statements and beliefs, however, remain themselves entirely unchanged; it is because the things change that the contrary comes about in the [statements or beliefs] about them; for the statement that someone is sitting remains the same, but it comes to be true at one time and false at another because the things change. It is the same with beliefs too. Thus, it would still be special about substance that it can receive contraries in this way—by a change in *itself*—even if one were to allow that statements and beliefs can receive contraries.

Yet even this is not true. For statements and beliefs are said to be receptive of contraries not because they receive any of the contraries in themselves, but because the affection comes to be in regard to something else. It is because of what the thing is, or is not, that a statement is said to be true or false, not because it can itself receive contraries; for, unconditionally speaking, no statement or belief is changed by anything at all. So since nothing happens to them, they are not receptive of contraries after all. But a substance receives contraries in itself, and this is the reason it is called "receptive of contraries"; for it receives illness and health, or paleness and darkness, and it is said to be receptive of contraries because it itself receives each such contrary. Thus, it is special to substance that something that remains the same and is one in number can receive contraries. Let this much, then, be said about substance.

6
Quantity

Some quantities are discrete, others are continuous. Some quantities are composed of parts which have a position in relation to each other, while others are composed without [such] a position.

Discrete quantities include, for example, number and speech; continuous ones include line, surface, body, and, in addition to these, time and place. For there is no common boundary of the parts of a number at which its parts meet—for example, if the parts of ten are fives, the two fives do not meet at a common boundary; rather, they are discrete. Nor do three and seven meet at a common boundary. And in general you cannot find a common boundary for the parts of any number—they are always discrete. So number is one of the discrete quantities. Similarly, speech is among the

discrete quantities. (That speech is a quantity is obvious, for it is measured by long and short syllables. Of course, I mean speech that is produced with a voice.) For their parts do not meet at any common boundary. There is no common boundary at which the syllables meet—but each in itself is discrete.

5a1 A line, on the other hand, is continuous; for there is a common boundary at which its parts meet—a point. And the parts of a surface meet at a line, for the parts of a plane meet at a certain common boundary. Similarly, for a body you can find a common boundary—a line or surface—at which the parts of the body meet. Time and place are also like this; for the present time meets both the past time and the future time. Place too is one of the continuous quantities; for the parts of a body occupy a certain place, and these parts meet at a certain common boundary. And so those parts of a place which each of the parts of a body occupies meet at the same boundary at which the parts of the body also meet. So place is also continuous; for its parts meet at one common boundary.

Further, some quantities are composed of parts which have a position in relation to each other, and some are not composed of parts which have [such] a position—for example, the parts of a line have a position in relation to each other; for each of them lies somewhere, and you can distinguish them and specify where on the plane each one lies and which of the remaining parts it meets. Similarly, the parts of a plane have a certain position; for you can specify in the same way where each one lies, and which ones adjoin each other. It is the same with both the parts of a solid and those of a place.

But the parts of a number, on the other hand, cannot be looked upon as having some position in relation to each other, or as lying somewhere, or as to which ones meet each other. Nor can the parts of time; for none of the parts of time endures, and how can what does not endure have any position? Rather, you might say that they have a certain order in that some parts of time are earlier and others later. And it is the same with number, in that in counting, one comes before two and two before three. Thus, numbers might have a certain order, but definitely you cannot find them having a position. It is the same with speech. For none of its parts endures—it is uttered, and then it is gone. So its parts do not have any position if none of them endures. Some quantities are composed of parts that have a position, then, while others are not composed of parts that have a position.

Only those we have mentioned are said to be quantities in the strict sense; all the others are said to be such coincidentally. For it is with an eye toward the ones we have mentioned that we also call the others "quantities." For example, there is said to be a **5b1** large amount of white insofar as the surface is large, and an action or a movement is said to be lengthy insofar as its duration is long. For it is not intrinsically that each of these is said to be a quantity—for example, if one were to give the quantity of some action, one would bound it temporally by specifying it as "yearlong," or something of the sort. And in speaking of a quantity of white, one would bound it by giving its surface; for of whatever size the surface is, one will say there is that much white. So

only those things we have mentioned are said to be quantities in the strict sense and intrinsically. Among the rest, none is a quantity intrinsically, but is so coincidentally, if at all.

Moreover, there is no contrary to a quantity. (It is clear that there is no contrary in the case of any of the definite quantities. There is, for example, nothing contrary to two cubits, three cubits, a surface, or anything like that.) But might not one say that many is contrary to few, or large to small? None of these, however, is a quantity; rather, they are relatives. For nothing is said to be large or small intrinsically, but only with reference to something else—for example, a mountain is called "small," and a millet seed "large," insofar as the latter is large among things of its kind, and the former small among things of its kind. There is, then, a reference to something else, since if a thing were said to be small or large intrinsically, the mountain would never be said to be small, or the millet seed large. Again, we say there are many people in the village, and few here in Athens—though there are many times as many here. And we say there are many in the house, and few here in the theater—though there are many more here. Further, two cubits, three cubits, and each thing of that sort signifies a quantity, but neither large nor small signifies a quantity; rather, each of them signifies a relative, for the large and the small are considered in relation to something else. So it is evident that they are relatives.

Further, whether one regards them as quantities or not, there is nothing contrary to them; for how can there be a contrary to what cannot be taken intrinsically, but only with reference to something else? Besides, if large and small are contraries, it will follow that the same thing at the same time admits of contraries, and that things will be their own contraries; for the same thing happens to be at the same time both large and small; for in relation to this it is small and in relation to that the very same thing is large. So it follows that the same thing happens to be both large and small at the same time, with the result that it admits of the contraries at the same time.

But it seems that nothing admits of contraries at the same time. Although a substance, for example, is thought to be able to receive contraries, it will certainly not be ill and healthy at the same time, nor white and black at the same time; nor does anything else admit of contraries at the same time. Otherwise, it turns out that some things are their own contraries; for if large is contrary to small and the same thing is at the same time large and small, that thing would be contrary to itself. But it is impossible that a thing should be contrary to itself. Therefore, large is not contrary to small, nor many contrary to few. So even if someone should say that these are not relatives but rather quantities, still they will have no contrary.

But it seems to be most of all with respect to place that there is contrariety of quantity; for people take *up* to be contrary to *down*, meaning by "down" the region toward the center, because the greatest distance is the one from the outer limits of the cosmos to the center. It seems likely that it is from these that they also derive their definition of other contraries; for they define as contraries things in the same kind that are at the greatest distance from each other.

It seems that a quantity does not admit of the more and the less—for example, one two-cubit length is not more two cubits than another. Nor does a number admit of more or less—for example, we do not say that three is more three than five, nor that one three is more three than another. Nor even is one time called "more" a time than another. Nor is any one of the items we have discussed said to be more or less. So quantity does not admit of the more and the less.

What is most special of all to a quantity is that it is said to be both equal and unequal. For each of the quantities we have discussed is said to be both equal and unequal. A body, for example, is said to be both equal and unequal; and a number is said to be both equal and unequal; and a time is said to be both equal and unequal. Similarly for the other things we have discussed, each is said to be both equal and unequal. Among the remaining things that are not quantities, it would seem that none is said to be both equal and unequal. A disposition, for example, is certainly not said to be equal and unequal, but rather similar; and white is certainly not both equal and unequal, but rather similar. So what would be most special of all to a quantity is that it is said to be both equal and unequal.

7
Relatives

The things that are said to be relatives are those that are said to be precisely what they are either *of* (or *than* or *to*)[15] other things or, in some other way, in relation to another thing. For example, what is larger is said to be precisely what it is *than* another—for it is said to be larger than something; and what is double is said to be precisely what it is *of* another—for it is said to be the double of something. It is the same with all other such things. Such things as a state, disposition, perception, scientific knowledge, or position are also to be included among relatives; for each of the aforementioned things is said to be precisely what it is (and not something else) *of* other things; for a state is said to be the state *of* something, scientific knowledge the scientific knowledge *of* something, a position the position *of* something, and so on for the rest. Relatives, then, are those things that are said to be precisely what they are *of* other things, or in some other way in relation to another thing. For example, a mountain is said to be large in relation to another [mountain] (for a mountain is said to be large in relation to something) and what is similar is said to be similar to something; and all things such as these are, in like manner, said in relation to something.

Lying, standing, and sitting are positions, and position is a relative. To be lying, to be standing, and to be sitting, however, are not positions, but things are so called paronymously after the aforementioned positions.

15. Aristotle does not give a list of prepositions; rather, he just uses the genitive *heterôn* ("other things").

There is also contrariety among relatives—for example, virtue is contrary to vice, each of which is relative to something, as scientific knowledge is to ignorance. But not all relatives have contraries; for nothing is contrary to double or triple or any other such thing.

Relatives seem to also admit of the more and the less; for what is similar is said to be more so or less so, and what is unequal is said to be more so or less so, and each of these is a relative—for what is similar is said to be similar *to* something, and what is unequal is said to be unequal *to* something. But not all relatives admit of the more and less; for what is double is not said to be more double or less double, nor is any other such thing.

Every relative is said to be related to things that are conversely related to it—for example, a slave is said to be slave of a master, and the master is said to be master of the slave; a double is said to be double of a half, and the half is said to be half of its double; and the greater is said to be greater than the lesser and the lesser is said to be lesser than the greater. It is the same with the rest. Sometimes, however, there will be a grammatical difference in case-ending[16]—for example, scientific knowledge is said to be scientific knowledge *of* what is scientifically knowable, and what is scientifically knowable is said to be scientifically knowable *by* scientific knowledge; and perception is called perception *of* what is perceptible, and what is perceptible is perceptible *by* perception.

Sometimes the converse will not seem to hold, if the speaker makes a mistake and does not give properly what a relative is said to be related to—for example, if a wing is given as being "of a bird," the bird is not conversely "of a wing";[17] for giving "wing of a bird" was not giving it properly in the first place. For it is not insofar as it is a bird that a wing is said to be a wing of it, but insofar as it is winged; for there are wings of many other things which are not birds. So if a relation is given properly, the converse also holds—for example, "a wing is the wing of what is winged" and "what is winged is winged thanks to a wing."

Sometimes it may be necessary to even make up a name, if there is no established name that properly gives what a relative is related to—for example, if you give "rudder of a boat," this is not done properly; for it is not insofar as it is a boat that a rudder is said to be the rudder of it; for there are boats which do not have rudders. Thus, the converse does not hold; for a boat is not said to be "boat of a rudder." But perhaps it would be giving it more properly if one were to give it in some way such as this: that a rudder is the rudder of (or in some other way related to) what is "ruddered" (there being no established name). And when given properly, the converse does hold—for what is ruddered is ruddered thanks to a rudder. It is the same with other cases. For

16. If *F*s are the *F*s of *G*s, it follows that *G*s are the *G*s of *F*s, but the expression for "of *F*s" in Greek may be either in the genitive case or in the dative case.

17. Aristotle later (8^a28–35) revises his definition of relatives, so that parts of things (wings, heads, hands, rudders, etc.) no longer count as relatives. He makes this point explicitly at 8^b15–19.

example, a head would more properly be given as the head of what is "headed" than as the head of an animal; for it is not insofar as it is an animal that it has a head; for many animals do not have a head. Thus, perhaps one would most easily grasp the things which do not have established names if one were to derive the names of the conversely related things from the names of the original relatives, just as, in the cases discussed, "winged" was derived from "wing" and "ruddered" from "rudder."

Thus, when properly given, every relative, *R*, is said in relation to something conversely related to it. Whereas, if we give it as being related to some random thing, rather than to the very thing in relation to which it is said, then the converse will not hold. I mean that not even among relatives, *R*, that are admittedly said in relation to things that are conversely related to them and have established names, will the converse hold, if these relatives are given as being related to coincidents rather than to the very things in relation to which they are so called. If "slave," for example, is given, not as "slave of a master," but as "of a human," or "of a two-footed [animal]," or something like that, then the converse will not hold; for this way of giving it is not proper.[18]

Further, if what a relative, *R*, is said in relation to is given properly, then, if all coincidents are taken away and all that is left is only that to which it is properly given as related to, it will always be said to be related to that—for example, if it is in relation to a master that someone is said to be a slave, then, if all coincidents attached to the master are taken away (such as his being two-footed, receptive of scientific knowledge, a human) and all that is left is that he is a master, the slave will always be said to be a slave in relation to that; for a slave is said to be slave of a master. But if what a relative, *R*, is so called in relation to is given improperly, then, if everything else is taken away and all that is left is only what it was given as related to, it will not be said to be related to that. For suppose you give "slave of a human" or "wing of a bird." Now, take away from the human his being a master. Then the slave will not be said to be a slave in relation to a human; for, if there is no master, there is no slave either. And in the same way, if you take away from the bird its being winged, the wing will not be a relative anymore; for, if there is nothing winged, there will not be a wing *of* anything either.

So one must give whatever a relative, *R*, is properly said in relation to. If there is an established name, this is easily done; if there is none, it may be necessary to make up a name. When names are given in this way, it is clear that every relative, *R*, will be said in relation to something conversely related to it.

It seems that relatives are by nature simultaneous. And in most cases this is true; for at the same time there is a double there is also a half, and when there is a half there is a double; and when there is a slave there is a master. The others too are like these.

18. I.e., for every relation, *R*, there is a converse relation, *Ř*, such that for any *x* and any *y*, *xRy* if, and only if, *yŘx*. Thus, for example, *the parent of* relation is the converse of *the child of* relation.

And the one does away with the other along with it; for when there is no double there is no half, and when there is no half there is no double. It is the same with others like these. But it does not seem to be true of all relatives that they are simultaneous by nature; for what is scientifically knowable would seem to be prior to scientific knowledge; for we gain scientific knowledge, for the most part, of already existing things. In few cases, or none at all, could one find scientific knowledge coming to be at the same time as what is scientifically knowable. Further, although when what is scientifically knowable has ceased to exist, it also makes scientific knowledge cease to exist along with it, scientific knowledge does not make what is scientifically knowable cease to exist along with it. For when there is nothing scientifically knowable there is no scientific knowledge—for there will no longer be scientific knowledge of anything—but nothing prevents there being something scientifically knowable when there is no scientific knowledge—for example, squaring the circle, if indeed it is scientifically knowable, is scientifically knowable even though there is as yet no scientific knowledge of it. Further, if an animal ceases to exist, there will be no scientific knowledge [of it], although there may be many things that are scientifically knowable.

The situation with perception is the same; for the perceptible seems to be prior to perception; for although when the perceptible ceases to exist, it makes perception cease to exist along with it, perception does not make the perceptible cease to exist along with it. For the perceptual modalities deal with bodies and are in bodies, and if something perceptible ceases to exist, a body will also cease to exist—for a body, too, is something perceptible—and if there were no bodies, perception would cease to exist. So perception ceases to exist along with the perceptible. But the perceptible does not cease to exist along with perception; for with the cessation of animal's existence, perception would cease to exist, but there would still be things that are perceptible, such as body, heat, sweet, bitter, and all other perceptible things. Further, perception comes into being at the same time as what is capable of perceiving—for animal and perception come into being at the same time—but the perceptible exists even before there is perception; for fire and water and the like, of which animals are composed, exist even before there is any animal at all, or any perception. So the perceptible would seem to be prior to perception.

There is a puzzle about whether, as it would seem, no substance is said to be among the relatives, or whether this is a possibility with respect to some secondary substances. It is true as far as primary substances are concerned, for neither wholes nor parts are said in relation to something. Thus, a particular human is not said to be a particular human of something, nor a particular ox a particular ox of something. It is the same way with parts; for a particular hand is not said to be a *particular* hand of something but rather a hand of something; and a particular head is not said to be a *particular* head of something but rather a head of something. It is the same with secondary substances, at least with most of them—for example, a human is not said to be a human of something, nor an ox, ox of something, nor a wooden

log, wooden log of something—but rather they are said to be someone's possession. In such cases as these, then, it is clear that substances are not relatives; but there is a dispute concerning some secondary substances. A head, for example, is called a head *of* something, and a hand, hand *of* something, and so on for similar cases. So these would seem to be relatives.

Thus, if the definition given[19] of relatives is sufficient, then it is either very difficult or else impossible to arrive at the solution that no substance is said to be a relative. However, if the definition is not sufficient, but rather relatives are those things the being for which is the same as their standing in a certain relation to something, then perhaps something might be said in reply. The earlier definition does indeed fit all relatives, but this—their being said to be precisely what they are *of* other things—is not what their being relatives consists in.

It is clear from these considerations that if one knows definitely that something is a relative, then one will know definitely what it is said in relation to. This is also self-evident. For if someone knows of a certain this something that it is a relative, and the being for relatives is the same as being somehow related to something, then one also knows what it is somehow related to; for if one does not know at all what it is somehow related to, then one will not know whether it is somehow related to anything. Clearly it is this way in particular cases—for example, if one knows definitely of a this something that it is a double, one will at once know definitely what it is the double of; for if there is no definite thing that one knows it to be the double of, one does not at all know whether it is a double either. Similarly, if one knows of a this something that it is better, one must know definitely what it is better than, because of this: it is not just that one will know indefinitely that it is better than something worse; for that sort of thing is a supposition, not scientific knowledge; for in that case one will not have an exact knowledge of its being better than something worse; it may happen that nothing is worse than it is. So it is evident that it is necessary for one who knows some relative definitely to also know definitely what it is said in relation to.

But now with respect to a head, a hand, and to each of the things that are substances, it is possible to know definitely what precisely it is; and it is not necessary to know what it is said in relation to. For it is not necessary to know[20] definitely whose head this is, or whose hand. So these would not be relatives. And if *they* are not relatives, it would be true to say that no substance is a relative.

It is perhaps difficult to give a strong opinion on such matters, if one has not gone over them many times. But to go through all the puzzles concerning each of them is not completely useless.

19. At 6^a36–37.

20. Reading οὐκ ἀναγκαῖον ἔστιν.

8
Quality

By "quality" I mean that in accord with which people are said to be of some sort.[21] But something is said to be a quality in many ways.

Let us say that a state or a disposition is one form of quality. States, such as the branches of scientific knowledge and the virtues, differ from dispositions in that they are more stable and longer-lasting; for scientific knowledge seems to be highly stable and hard to remove—even if one has a mediocre grasp of that scientific knowledge, granting that he suffers no great change through illness or something else of the same sort. And the same thing is true of virtue. Justice, for example, and temperance and each of the others, seem not easily removed or changed.

But things that are easily removed and quickly changed—heat, for example, and cold and illness and health and other things like that—are called "dispositions"; for a human being is disposed in some way in accord with these, but he changes quickly from hot to cold and from being healthy to being ill. It is the same with the rest, unless even one of these should happen, due to length of time, to have become natural and either incurable or extremely hard to remove, and then one might perhaps call it a "state." It is evident, though, that one tends to call "states" those things that are longer-lasting and harder to remove; for people who do not have a complete grasp of a branch of scientific knowledge, but rather change their minds easily, are not said to possess the state. And yet they are disposed in some way, better or worse, with respect to that scientific knowledge. So a state differs from a disposition in that the latter is easily removed, whereas the former is longer-lasting and harder to remove.

On the other hand, states are also dispositions, while dispositions are not necessarily states; for anyone in a state is thereby also disposed in some way in accord with it, whereas those who are disposed are not in every case in a state.

Another [second] kind of quality is that in accord with which we call people "good at boxing," "good at running," "healthy," or "sickly"—in a word, whatever they are said to be in accord with a natural capacity or incapacity; for one is said to be each of these things not because one is disposed in some way, but because one has a natural capacity to do something easily or not to be affected by something. For example, people are called "good at boxing" or "good at running," not because they are disposed in some way, but because they have a natural capacity to do something easily; and they are called "healthy" because they have a natural capacity not to be easily affected by what happens to them, and "sickly" because they have an incapacity for not being affected by something. Being hard and soft are similar; for a thing is said to be hard because it has the capacity to not be divided easily, and soft because it has an incapacity for the same thing.

21. 3^b16.

Affective qualities and affections make up a third kind of quality. Examples of these are sweetness and bitterness, sourness, and everything akin to these, and also heat and cold, and paleness and blackness. That these are qualities is evident; for it is in accord with them that what has taken them on is said to be of some sort—for example, honey is said to be sweet because it has taken on sweetness, and a body is said to be pale because it has taken on paleness. And it is the same with the others. They are called "affective qualities" not because what has taken on these qualities has been somehow affected—for honey is not said to be sweet because it has been somehow affected, nor is this the case with any other such thing. Similarly, heat and cold are called "affective qualities" not because what has taken them on is somehow affected, but it is because each of the qualities mentioned produces an affection in connection with the perceptual modalities that they are called "affective qualities"; for sweetness produces some affection in connection with taste, and heat one with touch, and similarly for the others.

Paleness and darkness and the other colors are called "affective qualities," not in the same way as those just mentioned, but because they are brought about by affections. Now, it is clear that many changes of color are brought about by an affection; for when one is ashamed one turns red, when one is afraid one turns pale, and so forth. And so if someone is by nature affected with any such affection, it makes perfect sense that he will have the associated color; for the same bodily disposition that now comes about when one is ashamed might also come about in accord with one's natural constitution, so that it might also be by nature that one comes to have the associated color.

Among these things that happen to one, those which originate from affections that are hard to remove and highly stable are called "qualities"; for if paleness or darkness comes about as part of one's natural constitution, it is said to be a quality (for we are said to be of some sort in accord with these); and if paleness and darkness have come about due to long illness or sunburn and are not easily gotten over, or even last through life, then these too are called "qualities" (for we are similarly said to be of some sort in accord with them). But those which come about from what is easily parted with and quickly gotten over are called "affections"; for people are not said to be of some sort in accord with them; for a person who turns red due to shame is not called "ruddy," nor is a person who turns pale due to fear called "pallid"; rather, they are said to have been affected by something. So such things are said to be affections, but not qualities.[22]

In much the same way we also speak of affective qualities and affections with regard to the soul. For those that come to be at the moment of birth as a result of some affection are called "qualities"—for example, mania and anger and the like; for in accord with

22. The earlier assertion that affective qualities and affections make up a third sort of quality (9ª28–29) should, perhaps, be taken to mean that those affections that are qualities constitute a third kind.

them people are said to be of some sort—angry or manic. It is the same with aberrations that are not congenital but come to be from something else that can happen to one and are either hard to get rid of or even completely irremovable: these too are qualities; for people are said to be of some sort in accord with them. But when they arise from what is quickly gotten over, they are called "affections," as when a person in pain is rather angry; for a person who is rather angry when in the grip of such an affection is not said to be an angry person, but rather is said to be affected by something. So such things are said to be affections, but not qualities.

Figure and the shape that belongs to each thing, and further, in addition to these, straightness and curvedness and if there is something similar to them, make up a fourth kind of quality; for in accord with each of these a thing is said to be of some sort; for a thing is said to be of some sort on account of being a triangle or a square, and also on account of being straight or curved, and each thing is said to be of some sort in accord with its shape.

Rare and dense and rough and smooth might seem to signify qualities. However, it seems that such things are foreign to a classification of qualities, for it appears rather that each of them indicates some arrangement of parts; for a thing is dense because its parts are close to each other, and rare because its parts are separated from each other; it is smooth because its parts lie somehow along a straight line, and rough because some parts stick out and others recede.

Perhaps some other mode of quality might be brought to light; but these are pretty much the ones mentioned most.

What we have mentioned above, then, are qualities; and things that are of some sort are those that are called in accord with them paronymously or else in some other way. In most cases, indeed in pretty much all cases, they are said of things paronymously—for example, a person is said to be pale from paleness or grammatical from grammar, and just from justice, and similarly for the rest. However, in some cases, when there are no established names for the qualities, it is not possible to be called something from them paronymously. For example, a person good at running or boxing,[23] who is so called in accord with a natural capacity, is not said to be such paronymously from any quality; for there are no established names for these natural capacities in accord with which people are said to be of some sort, as there are for the scientific knowledge from which people are called "expert boxers" and "expert wrestlers" in accord with a disposition. (For boxing is said to be scientific knowledge, as is wrestling, and it is from these paronymously that those who are so disposed are said to be of some sort.)

In some cases, even where there is an established name [for a quality], a thing that is said to be of some sort in accord with it is not so called paronymously—for

23. When the name *puktikos* is used to pick out a natural boxer, the person cannot be called a "boxer" paronymously from a natural talent because there is no name for such a talent. But when it is used to pick out an expert, the person is called a "boxer" paronymously after the science of boxing, for which there is a name (*puktikê*).

example, a person is not called "excellent" from the name "virtue"; for a person is said to be excellent due to having virtue, but is not so called paronymously from virtue. But it is not like this in many cases. So things that are called from the aforementioned qualities, either paronymously or from them in some other way, are said to be of some sort.

There is also contrariety in accord with quality. Justice, for example, is contrary to injustice, and paleness to darkness, and similarly for the rest, and also for things said to be of such-and-such a quality in accord with these; the unjust, for example, is contrary to the just, and the pale to the dark. However, it is not so in all cases; for nothing is contrary to red or to yellow or to similar colors, although they are qualities.

Moreover, if one of two contraries is a quality, the other will also be a quality. This is clear if we first consider the other categories. If, for example, justice is contrary to injustice and justice is a quality, injustice will be a quality too; for none of the other categories fits injustice—neither quantity nor relation nor place nor, in short, any such thing besides quality. And the same thing holds for other contraries in accord with quality.

Qualities also admit of the more and the less; for one thing is called "more" or "less" pale than another, and one thing more just than another. And a thing can become more so; for a thing that is pale is capable of becoming even paler.

Still, this is not so in all cases, but only in most; for one might raise a puzzle whether one case of justice can be said to be more a case of justice than another, and similarly concerning other dispositions. For some people dispute such claims; for they deny altogether that one case of justice can be called "more" or "less" a case of justice than another, or one case of health more or less a case of health than another, although they do say that one thing can have less health than another, and one thing less justice than another, and so on for grammatical knowledge and the other dispositions. But, at any rate, it is indisputable that the things called in accord with these admit of the more and the less; for one person can be called "more grammatical" than another, or "more just," or "healthier," and so on for the rest.

But triangle and square do not seem to admit of more, nor does any other figure; for things that admit of the account of a triangle or that of a circle are all equally triangles or circles, whereas none of the things that do not admit of it is called "more" [a triangle or a circle] than another; for a square is not more of a circle than an oblong is; for neither one admits of the account of a circle. And in general, unless two things both admit of the account of a given thing, neither one will be called "more" that thing than the other. Hence not all qualities admit of the more and the less.

None of the things so far mentioned is special to quality. But it is in accord with qualities alone that things are said to be similar or dissimilar; for one thing is not similar to another in accord with anything else except that in accord with which it is of some sort. So what is special about quality would be that it is in accord with it that things are said to be similar or dissimilar.

We need not be alarmed if someone should tell us that although we proposed to discuss quality we have also included many relatives; for states and dispositions are relatives. For in pretty much all such cases the kinds are so called in relation to something, but none of its particular [forms] is. Thus while scientific knowledge, which is a kind, is said to be precisely what it is *of* something else (for it is called a scientific knowledge *of* something), none of its particular [forms] is said to be precisely what it is *of* something else. For example, grammar is not said to be grammar of something, nor is music said to be music of something. But if these too are said in relation to something, then it will be in accord with the kind—for example, grammar is said to be the scientific knowledge of something, not the grammar of something; and music the scientific knowledge of something, not the music of something. So the particular [branches of scientific knowledge] are not relatives. But we are said to be of some sort in accord with the particular [branches of] scientific knowledge; for it is them that we do have—indeed, we are called "scientific knowers" on account of possessing one of the particular [branches] of scientific knowledge. So it would be the particular [branches of] scientific knowledge that are qualities, precisely those[24] in accord with which we are said to be of some sort; and these are not relatives.[25]

Still, if the same thing happens to be both a quality and a relative, it is not at all absurd for it to be included in both these kinds.[26]

9
Doing, Being Affected, and the Rest of the Categories

Both doing and being affected admit of contrariety and of the more and the less; for heating is contrary to cooling, and being heated to being cooled, and being pleased to being pained. So they admit of contrariety. But they also admit of the more and the less; for it is possible to heat more or less and to be heated more or less, and to be pained more or less. Thus doing and being affected admit of the more and the less.[27] **11^b1**

[This, then, is as much as is said about these matters. But on the topic of being arranged, it was remarked[28] (in the discussion of relatives) that things are said paronymously from positions. But about the rest—about when and where and having on—since they are quite perspicuous, nothing else is said about them except what

24. Reading καθ' ἅσπερ.
25. *Top*. $124^b15–22$.
26. *Met*. $1021^b3–8$.
27. Aristotle's discussion of individual categories breaks off at this point in an incomplete state. The following chapters (10–15) discuss various topics that pertain to more than one category. The remainder of 9 ($11^b10–16$), which serves as a transition to those chapters, along with the first sentence of 10 ($11^b15–16$), were probably inserted here by a later editor.
28. $6^b11–14$.

was said at the start[29] (that having shoes on and having armor on signify *having on*, and that in the Lyceum, for example, signifies *where*—and whatever else was said about these).]

10
Opposites

What has been said, then, about the kinds put forward is sufficient; but we have still to discuss opposites, and in how many ways things are usually opposed.

There are four ways in which things are said to be opposed to each other—either as relatives, as contraries, as privation and state,[30] or as affirmation and denial. To speak in outline about each of these ways of being opposed, an example of being opposed as relatives is double to half; as contraries, bad to good; as privation and state, blindness to sight; as affirmation and denial, he is sitting—he is not sitting.

Things opposed as relatives are said to be precisely what they are *of* their opposites, or in some other way in relation to them. For example, double is said to be precisely what it is—double—of half. Also, scientific knowledge and what is scientifically knowable are opposed as relatives, and scientific knowledge is said to be precisely what it is *of* what is scientifically knowable. And the scientifically knowable is said to be precisely what it is in relation to its opposite, scientific knowledge. For what is scientifically knowable is said to be scientifically knowable *by* something—by scientific knowledge. So things opposed as relatives are said to be precisely what they are *of* their opposites, or in some way *in relation to* each other.

Things opposed as contraries, however, while in no way said to be precisely what they are in relation to each other, are nonetheless said to be *contraries of* each other; for the good is not said to be the good of the bad, but the contrary of it; and the white is not said to be the white of the black, but its contrary. So these oppositions differ from each other.

When it is necessary for either one or the other of a pair of contraries to belong to the things in which they naturally occur, or of which they are predicated, there is no intermediate between them.[31] For example, illness and health naturally occur in the body of an animal, and it is necessary for either one or the other, either illness or health, to belong to the body of an animal; also, odd and even are predicated of numbers, and it is necessary for either one or the other, either odd or even, to belong to a number. And there is nothing at all intermediate between these, either between illness and health or between odd and even. But those of which it is not necessary for either one or the other to belong [to the things in which they naturally occur] do have

29. 2^a1–3.

30. There is an etymological connection between the noun *hexis* ("state") and the verb *echein* ("have") that is not apparent in the translation.

31. 12^a2–4 is secluded as an interpolation; it appears at 12^a9–11.

something intermediate between them. For example, black and white naturally occur in bodies, and it is not necessary for one or the other of them to belong to a body (for not every body is either white or black); also, while bad and good can be predicated both of humans and of many other things, it is not necessary for either one or the other of them to belong to those things of which they can be predicated; for not all of them are either bad or good. And there *is* something intermediate between these; for example, between white and black are gray and yellow and the other colors, between bad and good is what is neither bad nor good. In some cases there are established names for the intermediates, for example, gray and yellow between white and black; but in some cases, where it is not easy to link the intermediate to a name, the intermediate is specified by the denial of each of the extremes, for example, "what is neither good nor bad" and "what is neither just nor unjust."

Privation and state are so called in regard to the same thing—for example, "sight" and "blindness" in regard to the eye. To speak in universal terms, they are both said in regard to that in which the state naturally occurs. And we say that a thing capable of admitting a state is deprived of it if the state naturally belongs to that thing, but does not belong to it at all at a time when it would be natural for the thing to have it; for it is not what lacks teeth that we call "toothless," or what lacks sight that we call "blind," but what lacks these at a time when it would be natural for it to have them; for some things have neither sight nor teeth from birth, but they are not called "toothless" or "blind."

But being deprived is not a privation, and having a state is not a state; for sight is a state, and blindness is a privation, but *having* sight is not sight, and *being* blind is not blindness; for blindness is a certain privation, and being blind is being deprived of something, but it is not a privation. Further, if blindness were the same as being blind, both would be predicated of the same thing. But whereas a human being may be called "blind," a human being is in no way called "blindness." Yet it seems that these too—being deprived and having a state—are opposed as privation and state **$12^{b}1$** are; for the mode of opposition is the same—as blindness is opposed to sight, in just the same way being blind is opposed to having sight. Nor is what an affirmation or a denial is about an affirmation or a denial; for whereas an affirmation is an affirmative statement and a denial is a negative statement, none of the things an affirmation or a denial is about is a statement. Still, they too are said to be opposed to each other as affirmation and denial are; for in these instances too, the mode of opposition is the same; for in whatever way an affirmation and a denial—for example, "he is sitting" and "he is not sitting"—are opposed, that is the way the actual things each is about—the sitting and the not sitting—are also opposed.

It is evident that privation and state are not opposed as relatives; for neither is said to be precisely what it is *of* its opposite; for sight is not the sight *of* blindness, nor is it said in any other way in relation to it. Nor, in the same way, would blindness be said to be the blindness *of* sight, but rather blindness is said to be the privation of sight, not blindness of sight. Further, all relatives are said in relation to things conversely

related to them. So if blindness were a relative, then that in relation to which it is said would also be conversely related to it. But the converse does not hold; for sight is not said to be sight of blindness.

That things said as privation and state are not opposed as contraries either is clear from the following. Among contraries that have nothing intermediate between them, it is necessary for one or the other always to belong to the things in which they occur by nature, or of which they are predicated; for those with nothing intermediate between them were just those of which it is necessary that one or the other belong to what is receptive of them, such as with illness and health or odd and even. But of those that have something intermediate between them, it is never necessary for one or the other to belong to everything [receptive of them]; for it is not necessary that everything be white or black (or hot or cold) that is receptive of them; for there is nothing to prevent something intermediate between these from belonging. Further, those with something intermediate between them were just those of which it is not necessary that one or the other belong to what is receptive of them, unless there is one of them that belongs to those things by nature, as being hot belongs to fire and being white belongs to snow. And with these it is necessary that it be definitely one or the other that belongs, not just whichever one of them happens to do so; for it is not possible for fire to be cold, or for snow to be black. So it is not necessary for one or the other to belong to everything that is receptive of them, but only to those things to which one of them belongs by nature, and to which it is definitely one of them that belongs, and not whichever of the two happens to.

But neither of the things just mentioned is true of privation and state; for it is not necessary that one or the other of these always belongs to what is receptive of them; for a thing for which it is not yet natural to have sight is not said either to be blind or to have sight. So these would not be among the contraries that have nothing intermediate between them. Nor, however, would they be of the sort that do have something intermediate between them; for it is necessary that one or the other of them belongs at some time to everything receptive of them; for once it is natural for a thing to have sight, that thing will then be said either to be blind or to have sight; and not definitely one or the other of these, but whichever of the two happens to belong. For it is not necessary either for it to be blind or for it to have sight; rather, one or the other just happens to belong to it. But contraries with something intermediate between them were ones of which it is never necessary that one or the other belongs to everything [receptive of them]. Rather, they belong to some, and to these there is definitely one that belongs. So it is clear that things opposed as privation and state are opposed in neither of the ways in which contraries are.

Further, it is possible for there to be change from one contrary into the other as long as there is something to receive them—unless one of them belongs to something by nature, as, for example, being hot belongs to fire; for the healthy can become ill, and what is white can come to be black, and what is cold hot. And it is possible to come to be base from being excellent, and come to be excellent from being base.

(For a base person, if led into better ways of living and speaking, may show some improvement, even if only a little bit, toward being a better person. But if he should once improve a little, it is evident that he might change completely or improve a great deal; for even if he improves just a little from his starting-point, he keeps getting more inclined toward virtue, so that he is likely to improve even more. And if this keeps happening, he will be restored completely to the contrary state—if time is not exhausted.) But with privation and state it is impossible for there to be change into each other; for change comes to be from the state to the privation, whereas change from the privation to the state is impossible; for someone who has become blind does not see again, nor does a bald man recover his hair, nor does a toothless man grow teeth.

It is evident that things opposed as affirmation and denial are opposed in none of the ways we have discussed; for only with these is it always necessary for one of them to be true and one false. For neither with contraries, nor with relatives, nor with state and privation, is it necessary that always one be true and the other false. Health and illness, for example, are contraries; and neither one is either true or false. Similarly, double and half are opposed as relatives, and neither of them is either true or false. Nor are even those that are opposed as privation and state, for example, sight and blindness. In general, nothing said without any combination is either true or false; and all the things mentioned are said without combination.

Contraries said in combination might certainly seem to share this feature[32]—for "Socrates is well" is contrary to "Socrates is ill." But even with these it is not necessary that always one be true and the other false; for if Socrates exists, one will be true and one false, but if he does not exist, both will be false. For neither "Socrates is ill" nor "Socrates is well" is true if Socrates himself does not exist at all. With privation and state, if he does not exist at all, neither one is true, while if he does exist, it is not always the case that one or the other is true; for "Socrates has sight" is opposed to "Socrates is blind" as privation and state, and even if he exists it is not necessary for one or the other to be true or false (for when it is not yet natural for him to have [sight], both are false). And if Socrates does not exist at all, then again both are false, both "he has sight" and "he is blind." But with affirmation and denial it will always hold, whether he exists or not, that one is false and the other true; for with "Socrates is ill" and "Socrates is not ill," if he exists, it is obvious that one of them is true and the other false, and similarly if he does not exist; for if he does not exist, "he is ill" is false and "he is not ill" is true.[33] So the only things to which it would be special that always one of them is true and the other false are those opposed as affirmation and denial.

$13^{b}1$

32. I.e., that it is always necessary for one of them to be true and one false.

33. "Socrates is well" and "Socrates is ill" both assert that Socrates exists. If he exists, they have opposite truth values, which are determined by his health; if he does not exist, they are both false. Their negations ("Socrates is not well" and "Socrates is not ill") are merely denials of the corresponding affirmations. So while if he exists they have opposite truth values, if he does not exist they are both true.

11
Contraries

The contrary to a good thing is necessarily a bad thing. This is clear by induction—for example, illness is contrary to health, injustice to justice, cowardice to courage, and
14a1 similarly for the rest. But it is sometimes a good thing and sometimes a bad thing that is contrary to a bad thing; for excess, which is a bad thing, is contrary to deficiency, which is a bad thing. Likewise the mean, which is good, is contrary to both [excess and deficiency]. Although one may see this sort of thing in a few cases, in most cases
5 a good thing is always contrary to a bad thing.

Moreover, with contraries it is not necessary that, if one exists, the other will too; for if everyone were healthy, health would exist, but illness would not. Similarly, if everything were white, whiteness would exist, but blackness would not. Further, if
10 Socrates' being healthy is contrary to Socrates' being ill, and it is not possible for both to belong to him at the same time, if one of the contraries existed it would not be possible for the other to exist as well; for if it were the case that Socrates is healthy, it would not be the case that Socrates is ill.

It is clear that it is the nature of contraries to occur in things that are the same
15 either in form or in kind; for illness and health occur in the body of an animal, but whiteness and blackness simply in a body, and justice and injustice in a soul. And necessarily all contraries are either in the same kind or in contrary kinds or else they
20 are themselves kinds; for white and black, since their kind is color, are in the same kind; but justice and injustice are in contrary kinds, the kind of the former being virtue, and that of the latter being vice; and good and bad are not in a kind, but are
25 just themselves kinds of certain things.[34]

12
Priority

There are four ways in which one thing is said to be prior to another. First, and in the strictest sense, with respect to time, according to which[35] one thing is said to be older or more ancient than another (for it is because the time is longer that it is said to be older or more ancient). Second, where there is no converse of an implication
30 of existence—for example, one is prior to two; for if there are two things, it follows immediately that there is one, whereas if there is one, there are not necessarily two. So there is no converse implication: from the existence of the one, that of the other does not follow—and the one from which there is no converse implication of existence
35 seems to be prior. Third, a thing is said to be prior with respect to some order, as with

34. *Top*. 123b9–11.
35. Reading καθ' ὃν for καθ' ὃ.

the sciences and with speeches. For in the demonstrative sciences there is a prior and a posterior in order; elements[36] are prior in order to geometrical figures, and in grammar, letters are prior to syllables. It is the same with speeches, for the introduction is **14b1**
prior in order to the narration. Moreover, in addition to the ways we have mentioned, what is better or more estimable is thought to be prior by nature. Ordinary people are in the habit of saying that those they particularly esteem and love "have priority." 5
This is pretty much the least appropriate of the ways.

There are, then, this many ways of calling something "prior." But there would seem to be another way of being prior, in addition to the ones we have mentioned; for 10
even where there is a converse implication of existence, what is somehow the cause of the other's existence might reasonably be called "prior by nature." That there are such cases is clear; for there is a converse implication of existence between the existence of a human and a true statement about him; for if there is a human, the statement in 15
which we say that there is a human is true; and the converse certainly holds; for if the statement in which we say that there is a human is true, there is a human. But the true statement is in no way the cause of there being the thing, while the thing seems somehow to be the cause of the statement's being true; for it is in virtue of whether or 20
not the thing exists that the statement is said to be true or false. So there are five ways in which one thing might be called "prior" to another.

13
Simultaneity

The things said to be simultaneous unconditionally and in the strictest sense are those that occur at the same time; for neither of them is either prior or posterior to the other. 25
These are called "simultaneous with respect to time."[37] As to the things that are simultaneous by nature, they are the ones that have a converse implication of existence, so long as neither is the cause of the other's existence—for example, double and half; for with them there is a converse implication: if there is a double there is a half, and if there is a half there is a double—and neither is the cause of the other's 30
existence.

Coordinate subdivisions within the same kind are also said to be simultaneous by nature. They are said to be "coordinately subdivided" when they are distinguished from each other in accord with the same division; for example, the flying compared to the walking, and to the aquatic. These things are coordinately subdivided from 35
the same kind; for animal is divided into these—into the flying, the walking, and

36. *Met.* 1014b3–9.

37. The Greek words for prior, posterior, and simultaneous all have a (secondary) non-temporal, as well as a (primary) temporal sense. The English words "prior" and "posterior" parallel their Greek counterparts in this respect; "simultaneous" does not, but must be read here as if it did.

the aquatic—and none of them is prior or posterior; rather, such things seem to be simultaneous by nature. Each of these—the flying, the walking, and the aquatic—
15a1 might be further divided into forms. Thus, these things too, which are marked off by the same division of the same kind, will be simultaneous by nature. But kinds are
5 always prior to forms; for they do not have a converse implication of existence—for example, if there is an aquatic animal, there is an animal; but if there is an animal, there is not necessarily an aquatic animal.

So the things said to be simultaneous by nature are all those that have a converse implication of existence, so long as neither is in any way the cause of the other's
10 existence, and coordinate subdivisions from the same kind. But things that are simultaneous unconditionally are those that occur at the same time.

14
Forms of Movement

There are six forms of movement: coming to be, passing away, increase, decrease, alteration, and change with respect to place.[38] That the remaining cases[39] of move-
15 ment are distinct from each other is evident; for coming to be is not passing away, nor is increase, nor is decrease,[40] nor is change with respect to place, and similarly for the rest. But about alteration there is a puzzle as to whether it might perhaps be necessary for what is altering to be altering in accord with one of the remaining sorts of movement.

20 However, this is not true; for with pretty much all affections, or most of them, we undergo alteration but partake of none of the other sorts of movement; for what is moved with respect to some affection does not necessarily increase or decrease, and so
25 on for the others. So alteration would be distinct from the other sorts of movement; for if it were the same, what is being altered would straightaway have to be increasing too, or decreasing, or one[41] of the other forms of movement would follow; but this is not necessarily so. Similarly, what is increasing, or being moved in some other sort of movement, would also have to be altering. But there are things that increase without
30 altering; for example, a square grows when a gnomon is put around it, but is not at all altered. Similarly too with other such cases. So the sorts of movement are distinct from each other.

15b1 Movement, simply speaking, is contrary to rest. But among particular kinds of movement, passing away is contrary to coming to be, and decrease is contrary to increase; and what seems most opposed to change with respect to place is rest
5 with respect to place, unless perhaps it is change to the contrary place (for example,

38. I.e., movements or changes with respect to substance, quantity, quality, and where.
39. I.e., those other than alteration.
40. Reading ἡ αὔξησις οὐδὲ ἡ μείωσις.
41. Reading τινι.

upward is contrary to downward, and downward to upward). But it is not easy to say what precisely is contrary to the remaining one[42] of the movements we have presented; it seems that nothing is contrary to it, unless in this case too one opposes it either to rest with respect to quality or to change to the contrary quality—in the same way that in the case of change with respect to place there is either rest with respect to place or change to the contrary place. For alteration is change with respect to quality, and so what is opposed to a change with respect to quality is either rest with respect to quality or change to the contrary quality (as, for example, coming to be white is opposed to coming to be black); for things are altered when change occurs into contrary qualities.

15
Having

Having[43] is said of things in several ways: having as a state, disposition, or some other quality (for we are said to have scientific knowledge and virtue); having as a quantity—for example, the height someone happens to have (for he is said to have a height of three cubits or four cubits); having as things on the body—for example, a cloak or a tunic; having as a thing on a part—for example, a ring on the hand; having as a part—for example, a hand or a foot; having as in a container—for example, a bushel of wheat or a jug of wine (for the jug is said to have wine, and the bushel to have wheat—they are thus said to have these as in a container); having as a possession (for we are said to have a house or a field). We are also said to have a wife, and a wife to have a husband. But the last-mentioned mode of "having" seems to be rather far-fetched; for by "he has a wife" we signify nothing other than that he lives with her in wedlock. There might perhaps turn out to be some other modes of having, but pretty much all of the ways in which it is customarily said of things have been enumerated.

42. I.e., alteration.

43. The *having* under discussion here is not, properly speaking, the category of "having on" (1ᵇ27), as is made clear by the list of ways of "having," which is cross-categorial.

DE INTERPRETATIONE*

1
Introduction

First, we must lay down what a name is and what a verb is, then what a negation, an affirmation, an assertion, and a saying are. **16ª1**

Voiced expressions are tokens for affections in the soul, and written expressions are tokens for voiced expressions. And as letters are not the same for all, neither are voiced sounds the same. But the primary items of which these expressions are signs are affections of the soul, which are the same for all, and those of which these are likenesses are objects, which are already the same. These matters have been discussed in *De Anima*;[1] for they belong to a different study.

Anyway, as in the soul there is sometimes a thought without being true or false and sometimes instead one which is such that one of the two necessarily holds of it, likewise among voiced sounds; for falsity and truth have to do with composition and division. Names and verbs by themselves are similar to the kind of thought which is without composition and division—for example, "human" or "pale" when nothing is added; for they are not yet false or true; they are, however, signs of a specific thing.[2] For even "goat-stag" does signify something, but is not yet true or false, unless "to be" or "not to be" is added, either unconditionally or with reference to time.

2
The Name

A name is a voiced sound significant by convention, not involving time, no part of which is significant in separation. For in "Whitfield," "-field" does not signify anything in its own right, as it does in the saying "white field."[3] However, the case of simple names is different from that of complex ones. For in the former the part is in

* Translated by Francesco Ademollo and Paolo Fait. Text: L. Minio-Paluello, *Categoriae et Liber De Interpretatione* (Oxford, 1956), in consultation with H. Weidemann, *De Interpretatione* (Berlin, 2014). The Greek title *Peri hermêneias*—probably not Aristotelian—means *On Linguistic Expression*. But Boethius' questionable translation of *hermêneia* as *interpretatio* ("interpretation") has become canonical.

1. The reference may be to *DA* 3.4–5, 7–8 (on understanding receiving the intelligible form of its object) or to 3.6 (on simple and compound thoughts).

2. Reading ἀληθές πω, σημεῖον with Weidemann.

3. Aristotle's example is *Kallippos*, a proper name derived from a contraction of the phrase *kalos hippos*, "noble horse."

no way significant, whereas in the latter it has a meaning, but not in separation from anything—for example, "plum-" in "plumcot."[4]

"By convention" means that no name is such by nature, but only when it becomes a token. For also unlettered sounds, for example, those of beasts, do indicate something—and yet none of them is a name.

"Not-human" is not a name. There is, however, no name established by which one should call it; for it is neither a saying nor a negation. Let us call it an "indefinite name."

Philônos ("Philo's"), *Philôni* ("to Philo"), and the like are not names but inflections of a name. The account of this variety goes in the same way in the other respects, except that when combined with "is," "was," or "will be" it is not true or false (whereas the name always is). For example, "Philo's is" or ". . . is not": here there is not yet anything true or false.

3
The Verb

A verb is what additionally signifies time, no part of which is significant separately; and it is always[5] a sign of the things said of something other. I say that it additionally signifies time—for example, "recovery" is a name, but "recovers" is a verb, because it additionally signifies the thing's holding now. And it is always a sign of the things which are said of something other, that is, are said of a subject or in a subject.[6]

"Doesn't-recover" and "doesn't-ail" I do not call verbs. For although they additionally signify time, and always hold of something, there is no established name for their difference.[7] Let us call them "indefinite verbs," because they hold in the same way of any sort of thing: both of something that is and of something that is not.

Likewise, "recovered" and "will recover" are not verbs, but inflections of a verb. They differ from the verb because the verb additionally signifies the present time, whereas inflections additionally signify the time outside the present.

When uttered just by themselves verbs are names and signify something—for the speaker arrests the thought and the hearer pauses—but they do not yet signify whether it is or is not. For not even[8] "to be" or "not to be" is a sign of the thing—not even if

4. Aristotle's example is *epaktrokelês*: a hybrid kind of ship, partly similar to a kind of ship called *epaktris*, partly similar to a different kind called *kelês*. Likewise, a plumcot is a hybrid between a plum and an apricot.

7. I.e., we lack a term to identify this as a specific kind of verb.

8. Reading οὐδὲ.

you say "what is" just by itself alone.[9] For by itself it is nothing, but it additionally signifies some composition, which cannot be thought of without the components.

4
The Saying

A saying is a significant voiced sound, some part of which is significant in separation—as a phrase but not as an affirmation. I mean, for example, that "human" signifies something, though not that it is or is not (there will instead be an affirmation or negation if something is added), but not a single syllable of "human." For even in "mice," "ice"[10] is not significant but is, in that context, a mere voiced sound. (In double names, instead, the part signifies, but not by itself, as was said.[11])

Every saying is significant—not, however, as an instrument, but by convention, as was said.[12] However, not every saying is assertoric, but only that in which being **17ª1** true or being false holds. And they do not hold in all sayings—for example, a prayer is a saying, but is neither true nor false. Let us leave aside the others, then, for their examination is more appropriate to rhetoric or poetry. The assertoric one, by contrast, belongs to the present theoretical investigation.

5
Assertoric Sayings: One and Many, Simple and Compound

The first assertoric saying that is a single one is the affirmation, then the negation; the others are one in virtue of a connective. Necessarily, every assertoric saying contains a verb or an inflection [of a verb]. For even the definitional saying of human, unless "is" or "will be" or "was" or some such thing is added, is not yet an assertoric saying. (Explaining why "terrestrial two-footed animal" is one and not many—for it will not be one just in virtue of being spoken together—is a matter for another inquiry.)[13]

An assertoric saying is a single one if it either indicates one thing or is one in virtue of a connective; many are either those which indicate many things and not one or those without a connective. (Let us consider the name and the verb as just a phrase, because it is not possible to say it, indicating something with one's voiced sound, in such a way as to make an assertion, whether in response to a question raised by someone or rather of one's own deliberate choice.)

9. Reading αὐτὸ καθ' αὑτὸ ψιλόν with Weidemann.
10. Aristotle's example is *mus* ("mouse") and *us* ("pig").
11. 16^a21–22.
12. 16^a19, 25–29.
13. *Met.* 7.12, 8.6.

Of these, one is a simple assertion, that is, something about something or something away from something, whereas the other is composed of these, that is, a saying which is already composite. The simple assertion is a significant voiced sound about whether something holds or does not hold, according to the divisions of time.

6
Affirmation, Negation, and Contradiction

An affirmation is an assertion of something about something; a negation is an assertion of something away from something. And since it is possible to assert of what holds that it does not hold, of what does not hold that it holds, of what holds that it holds, and of what does not hold that it does not hold (and similarly for the times outside the present), it must be possible to deny anything one has affirmed and to affirm anything one has denied. So it is clear that any affirmation has an opposite negation and any negation has an opposite affirmation. And let a contradictory pair be this: an affirmation and a negation opposite to each other. By "opposite" I mean that of the same thing about the same thing, but not homonymously, and all the other specifications of this sort which we add against the annoying objections of the sophists.

7
Universal and Particular Things; Universal, Non-universal, and Particular Assertions

Since among things some are universal, others are particular (I call "universal" what is of a nature to be predicated of a plurality of things, "particular" what is not—for example, human is a universal, Callias a particular), it is necessary to assert that something holds or does not hold either of some universal or of some particular. So, if one asserts universally about a universal that something holds or does not hold, there will be contrary assertions (by "asserting universally about a universal" I mean, for example, "Every human is pale" or "No human is pale"). When, on the other hand, one makes an assertion about universals, but not universally, the assertions are not contrary, but the things indicated may be contrary (by "making an assertion about universals not universally" I mean, for example, "A human is pale," "A human is not pale": "human" is universal, but one does not treat the assertion as universal; for "every" does not signify a universal, but that something holds, or does not hold, universally).

To predicate a universal universally about a subject of predication is not true. For there will be no affirmation in which a universal is predicated universally of the subject of a predication—for example, "Every human is every animal."[14]

14. I.e., the universal quantifier "every" should not be attached to the *predicate* term.

I say that an affirmation is contradictorily opposed to a negation when one signifies of a universal that something holds, or does not hold, of it universally, while the other signifies of the same universal that something holds, or does not hold, of it not universally[15]—for example, "Every human is pale," "Not every human is pale," "No human is pale," "Some human is pale." Contrarily opposed to each other are the universal affirmation and the universal negation[16]—for example, "Every human is just," "No human is just." These, therefore, cannot be true at the same time, whereas those opposed to them may be true [at the same time] about the same thing—for example, "Not every human is pale" and "Some human is pale."

Of all contradictory pairs concerning universals spoken of universally, then, necessarily one member is true and the other false. The same goes for those contradictory pairs that are about particulars—for example, "Socrates is pale," "Socrates is not pale." However, in the case of those contradictory pairs which are about universals not spoken of universally, it is not always the case that one is true and the other is false. For it is true at the same time to say "A human is pale" and "A human is not pale," and "A human is beautiful" and "A human is not beautiful."[17] (For if it is ugly, then it is also not beautiful; and if it is becoming something, then it also is not that thing.) This might seem absurd at first glance, because "A human is not pale" appears to signify also, at the same time, that no human is pale. But it does not signify the same, nor does it necessarily hold at the same time.

Clearly, one single affirmation has one single negation: for the negation must deny the same thing as the affirmation affirmed, and away from the same thing, whether this is particular or universal, and whether universally or not universally; I mean, for example, "Socrates is pale," "Socrates is not pale." If one instead denies something other, or the same thing away from something other, it will not be the opposite assertion, but a distinct one. The opposite of "Every human is pale" is "Not every human is pale," that of "Some human is pale" is "No human is pale," and that of "A human is pale" is "A human is not pale."

We have said, then, that one single affirmation is contradictorily opposed to one single negation, and what these are, and that contraries are distinct, and what these are, and also that not every contradictory pair has one true and one false member, why this is, and when it is has one true and one false member.

15. Reading τὴν τὸ καθόλου <ὅτι καθόλου> σημαίνουσαν <τῇ> τὸ αὐτὸ ὅτι οὐ καθόλου with Weidemann.

16. Reading τὴν καθόλου κατάφασιν καὶ τὴν καθόλου ἀπόφασιν.

17. These sentences are "indeterminate" (*APr.* 24^a19–20) and so can be used as equivalent either to particular or to universal sentences.

8
The Unity of Affirmations and Negations

A single affirmation and negation is one that signifies one thing of one thing, either a universal taken universally or not universally. For example, "Every human is pale" / "Not every human is pale"; "A human is pale" / "A human is not pale"; "No human is pale" / "Some human is pale," if "pale" signifies one thing. But if a name is given to two things from which no unity is formed, there is not a single affirmation nor a single negation.[18] For example, if someone were to give the name "cloak" to a horse and a human, "A cloak is pale" would not be a single affirmation. Saying this would not differ at all from saying "A human and a horse is pale" and this does not differ at all from saying "A horse is pale" and "A human is pale." If, then, these affirmations signify many things and are many, it is clear that also the first one signifies either many things or nothing. For no human is a horse. As a consequence, not even in these is it necessary that one part of the contradictory pair is true and the other false.

9
Assertions about Future Particular Events

With regard to things that are or have come to be, necessarily the affirmation or the negation about them is true or false. And as regards universals spoken of universally, necessarily it is always the case that one assertion about them is true and the other false, and as regards particulars too, as we have said,[19] while as regards universals spoken of not universally it is not necessarily so; we have discussed these too.[20]

However, with regard to particulars that are going to be, matters are not the same. For if every affirmation or negation is true or false, then it is also necessary for everything to hold or not to hold. So, if[21] someone will say that something will be and someone else will say of this same thing that it will not be, clearly it is necessary for one or the other of them to be speaking truly—if every affirmation is true or false. For both will not hold at the same time in such cases. For if it is true to say that it is pale, or that[22] it is not pale, then necessarily it is pale, or not pale, and if it is pale, or not pale, then it is true, as we have just said, to affirm or deny it; and if it does not hold, one is speaking falsely, and if one is speaking falsely, it does not hold. So, necessarily, either the affirmation or the negation is true. Therefore, nothing is or comes to be, nor will be or not be, by luck, or in whichever of the two ways it happens to, but everything of necessity and not in whichever of the two ways it happens to. For either

18. Reading οὐδὲ ἀπόφασις μία with Weidemann.
19. 17b27–29.
20. 17b29–34.
21. Reading ὥστε εἰ with Weidemann.
22. Reading ἢ ὅτι with Weidemann.

the one who affirms or the one who denies is speaking truly. For otherwise things might equally well come to be or not come to be; for what is in whichever of the two ways it happens to, is, or will be, no more so than not so.

Further, if something is pale now, it was true to say beforehand that it would be pale; so it was always true to say of whatever of the things which have come to be that it would be. And if it was always true to say that it was or would be, it is not possible for this not to be, or not to be going to be. But if something is such that it is not possible for it not to come to be, it is impossible for it not to come to be; and if it is impossible for something not to come to be, it is necessary for it to come to be. For all things that will be, then, it is necessary to come to be. Therefore, nothing will be in whichever of the two ways it happens to be or by luck; for if by luck, then not of necessity.

However, it is also not possible to say that neither of the two is true, that it will neither be nor not be. For, first, in such a situation, while the affirmation is false, the negation is not true, and while the latter is false, the affirmation turns out not to be true. In addition, if it is true to say that it is pale and large,[23] then both must hold, and if it is true to say that they will hold tomorrow, then they will have to hold[24] tomorrow. But if tomorrow it will neither be nor not be, then this would not be a case of things being in whichever of the two ways it happens to be. Take, for example, a sea battle: the sea battle would have neither to come to be nor not to come to be.

These, then, and other things of this sort, are the absurdities which result if, in every pair consisting of an affirmation and a negation that are opposite to each other, whether about universals spoken of universally or about particulars, necessarily one is true and the other is false: among the things which come to be, nothing is in whichever of the two ways it happens to be, but everything is and comes to be of necessity; as a consequence, there would be no need to deliberate or worry that, if we do this, this will be, but if we do not do this, it will not be. For nothing prevents someone from affirming that this will be in ten thousand years and someone else from denying it; so, whichever of the two was true to say then, will be of necessity. In fact, this makes no difference either, whether or not any people actually say the two contradictories; for clearly this is how things are even if it is not the case that someone affirms and another denies. For it is not because someone affirms or denies that it will be or not be, nor in ten thousand years rather than after a period of time of any length whatsoever. So, if during any interval of time[25] the state of things was such that one or the other was true, then it was necessary for this to come to be, and each of the things that come to be was[26] always in such a state as to come to be of necessity. For if someone said truly of something that it would be, it is not possible for this not to come to be; and of what comes to be it was always true to say that it would be.

23. Reading μέγα with Weidemann.
24. Reading ὑπάρξειν with Weidemann.
25. Reading ἐν ἅπαντι χρόνῳ with Weidemann.
26. Reading εἶχεν with Weidemann.

These things, then, are impossible. For we see that the starting-point of the things that will be is from both deliberation and action, and that, in general, in the things which are not always in activity there is the possibility of being and not being, and that in them both being and not being are admissible, and so also are coming to be and not coming to be—and in many cases it is clear to us that things are in this way: for example, it is possible for this cloak to be cut up, and yet it will not be cut up, but will wear out beforehand; and it is also equally possible for it not to be cut up, for wearing out beforehand would not hold of it, if it were not possible for it not to be cut up; so the same goes also for all the other comings to be spoken of in accord with this sort of possibility—it is evident, therefore, that not everything is or comes to be of necessity; rather, in some cases things are in whichever of the two ways they happen to be and neither the affirmation nor the negation is more true, whereas in other cases one of them is more true and one alternative comes to be for the most part, but, nonetheless, it is admissible also for the other and not the former to come to be.

What is necessarily is, when it is, and what is not necessarily is not, when it is not. Nonetheless, it is not the case that everything that is, necessarily is, or that everything that is not, necessarily is not. For it is not the same for everything that is to be of necessity when it is and to be unconditionally of necessity; and similarly with what is not. The same account applies to a contradictory pair. Everything necessarily is or is not, and will be or will not be; nonetheless, if one divides and says one or the other member of the pair, it is not the case that that is necessary.[27] I mean that, for example, necessarily there will be a sea battle tomorrow or there will not be one, and yet it is not necessary for a sea battle to come to be tomorrow, nor for it not to come to be; it is, however, necessary for it either to come to be or not to come to be.

So, since sayings are true in the same way as things, clearly whenever things are in such a condition that they are in whichever of the two ways it happens to be and contraries are admissible, the contradictory pair is necessarily in the same condition. This is precisely what happens in the case of the things that not always are or not always are not; for concerning these necessarily one or the other member of a contradictory pair is true or false—not, however, this or that, but whichever of the two it happens to be—and one of the two is more true than the other, but not thereby true or false. So it is clear that it is not necessary that, in every pair consisting of an affirmation and a negation opposite to each other, one should be true and the other false. For the case of the things that are is not like that of the things that are not, but are such that it is possible for them to be or not to be; the case of the latter is rather as we have said.

27. Cf. *SE* 166a23–32.

10
Affirmations and Negations with Indefinite Names and Verbs

Since an affirmation signifies something about something, and the latter is either a name or a "not-name," and what is in an affirmation must be one thing and about one thing (what a name is, and what the not-name, was stated previously;[28] for I do not call "not-human" a name, but an indefinite name—since it somehow signifies one indefinite thing—just as I do not call "does not recover" a verb[29]), every affirmation will be composed either of a name and a verb or of an indefinite name and a verb. Without a verb there is no affirmation or negation, for "is," "will be," "was," "comes to be," and the like are all verbs according to what we have laid down,[30] for they additionally signify time. So the first affirmation and negation are: "A human is" / "A human is not"; then "A not-human is" / "A not-human is not." Again, "Every human is" / "Every human is not"; "Every not-human is" / "Every not-human is not." The same holds for the times outside the present.

When "is" is predicated in addition as a third element, the oppositions are expressed in two ways.[31] I mean, for example, "A human is just": I say that "is" enters the composition as third name or verb[32] in the affirmation. So because of this there will be four cases, two of which will be, with regard to the sequence of affirmation and negation, in the way privations are, while two will not.[33] I mean that "is" will be added either to "just" or to "not-just," and so too will the negation. They will thus be four. Let us understand what has been said on the basis of the diagram below:

[A] A human is just	[B] Negation[34] A human is not just
[D] Negation[35] A human is not not-just	[C] A human is not-just

28. $16^a29–32$.
29. $16^b11–14$.
30. $16^b6–10$. At $16^b16–19$ verbs in tenses other than the present were described as "not verbs, but inflections of a verb."
31. I.e., depending on whether the negation is formed by adding the negation to "is" ("is-not just") or to the complement ("is not-just").
32. Aristotle's point seems to be that "is" is a third element in the set of names and verbs forming the affirmation.
33. Aristotle mentions privations (e.g., "unjust," "unequal") not because they are relevant here, but because, in the square diagram he uses as a model, affirmation and negation of a privative term appear in inverted order under affirmation and negation of the corresponding positive term.
34. I.e., of A.
35. I.e., of C.

In these cases "is" and "is not" are added to "just" and "not-just." As explained in the *Analytics*,[36] these cases are arranged in this way. Likewise too, if the affirmation is about the name taken universally—for example,

[A]	[B]
Every human is just	Not every human is just
[D]	[C]
Not every human is not-just	Every human is not-just

Here, however, the assertions on the diagonal cannot, in the same way, be true together, though they sometimes can.[37]

These, then, are two pairs in opposition. There are other oppositions if the addition is made to "not-human" as a sort of subject:

[A]	[B]
A not-human is just	A not-human is not just
[D]	[C]
A not-human is not not-just	A not-human is not-just

20^a1 There will not be any more oppositions than these, and these latter are a case of their own, separate from the previous ones, since they employ "not-human" as a name.

In all those cases where "is" does not fit (for example, with "to recover" or "to walk") the verbs produce the same result when they are placed in the same way as if "is" were added—for example: "Every human recovers" / "Every human does not recover."[38] "Every not-human recovers" / "Every not-human does not recover." For[39] one must not say "not-every-human" but add "not"—the negation—to "human." For "every"

36. At *APr*. 51^b36–52^a17 (cf. *Cael.* 282^b25–283^a1), Aristotle describes a square diagram with schematic term-letters arranged in chiastic order:

Affirmation (A)	Negation (B)
Negation (D)	Affirmation (C)

The purpose of the inversion was probably to achieve a perspicuous representation of certain logical relations in the diagram. The translation displays this and the following diagrams in that order, with the lettering of *APr*. added in square brackets.

37. A and C are mutually incompatible, while B and D are compatible. This differs from the previous diagram where both pairs are trivially compatible because their subject ("a human") is not taken universally.

38. This is the contrary, not the contradictory negation that we would expect in analogy with the quartets that precede, but Aristotle is referring back to 19^b17, and there too he phrases the negation of "Every human is" as the contrary ("Every human is not") rather than the contradictory ("Not every human is"). Although the reason is not clear, it is worth noting that here, at 19^b17, and at 20^a10–11 Aristotle is not displaying the oppositions as a square diagram.

39. I.e., in cases C and D.

does not signify the universal but that it is taken universally. This is clear from the following: "A human recovers"/ "A human does not recover." "A not-human recovers" / "A not-human does not recover." These cases differ from the previous ones in not being universal; thus "every" or "no" adds nothing to the signification other than that one affirms or denies universally about the name; hence the other elements must be added in the same way.[40]

Since the assertion signifying that no animal is just is the contrary negation of "Every animal is just," it is clear that these will never be true at the same time nor about the same thing, but their opposites[41]—"Not every animal is just" and "Some animal is just"—sometimes will. There are these consequences: "No human is just" follows from "Every human is not-just"; while the opposite of the latter, that not every human is not-just, follows from "Some human is just" (for there must be one).

It is also clear that, regarding particulars, if it is true to answer a question in the negative, it is also true to affirm—for example, "Is Socrates wise?" "No." "Therefore, Socrates is not-wise." Regarding universals, on the other hand, the affirmation phrased like the last one is not true, but the negation is true—for example, "Is every human wise?" "No." "Therefore, every human is not-wise." For this is false, while "Therefore, not every human is wise" is true. This is the opposite, whereas the other is the contrary.

Those opposite expressions that consist in indefinite names and verbs, such as "not-human" and "not-just," may seem to be negations without a name and a verb. But they are not. For a negation must always be true or false, while unless something else is added, someone who says "not-human" has no more said something true or false than someone who says "human"—indeed rather less so.

"Every not-human is just" does not signify the same as any of the above, nor does its opposite, "Not every not-human is just." "Every not-human is not-just" instead signifies the same as "No not-human is just."[42]

When names and verbs are transposed, they signify the same—for example, "A human is pale," "Pale is a human."[43] For if this is not the case, there will be more negations of the same affirmation; but it has been shown[44] that there is one negation of one affirmation. For the negation of "A human is pale" is "A human is not pale." The negation of "Pale is a human," if this is not the same as "A human is pale," will be either "Pale is not a not-human" or "Pale is not a human." But the former is the negation of "Pale is a not-human," the latter of "A human is pale." So they will be

40. I.e., by placing the negation sign "not" immediately before the subject noun of C and D.
41. I.e., the contradictory opposites.
42. Aristotle may be indicating that with negated subjects ("not-human"), there are no inferences like those mentioned at $20^{a}20$–23.
43. The transposition of "pale" and "a human" does not affect their syntactic roles. In either case "A human" is meant as the subject and "is pale" as the predicate.
44. $17^{b}37$–$18^{a}7$.

two negations of one affirmation. It is clear, then, that if the name and the verb are transposed, the same affirmation and negation result.

11
Single and Multiple Affirmations and Negations

Affirming or denying one thing about many, or many things about one, is not one affirmation or negation, unless what the many constitute is some one thing. And I do not call it "one" if there is one name established but they fail to constitute one thing.[45] For example, human is perhaps animal, and two-footed, and tame, but these items also constitute one thing, whereas pale, and human, and walking do not constitute one thing. So if someone affirms some one thing about these, it is not one affirmation: it is one voiced sound, but several affirmations. Likewise, if these are affirmed about one thing, this is several affirmations too. If, then, a dialectical question[46] is the request for an answer that is either the proposition at stake or one member of a contradictory pair (and if the proposition is a member of one contradictory pair), there will be no one answer in these cases (for the question is not one either), not even if it is true.[47] This is discussed in the *Topics*.[48] At the same time it is clear that the question "What is it?" is not dialectical either. For the question must give one the choice of asserting whichever member of the contradictory pair one wishes. The questioner must specify in addition whether human is this or not this.

Since of things predicated separately, some are also predicated in combination, the whole predicate being as one, while others are not, what is the difference? For of human it is true to say "animal" separately, and "two-footed" separately, and also to say them as one. Likewise, "human" and "pale," and these too as one. But it is not the case that if someone is good and a cobbler, he is also a good cobbler. For, if it is assumed that, because something is each of two things, it is also what is formed by both together, many absurdities will follow. For since of a human both "human" and "pale" are true, so also is the compound; again, if "pale," then also the compound. So he will be a pale pale human, and so on without limit. And again a musical pale walking one, and then these compounded many times over. In addition, if Socrates is Socrates and is a human, he is also Socrates human, and if he is a human and two-footed, he is a two-footed human.

It is clear, then, that if one unconditionally sets down that compounds come about, one ends up making many absurd claims. Let us now state how the matter must be set down.

45. Cf. $18^{a}18$–26.
46. *Top.* 1.10–11.
47. I.e., even if a question that lumps together several questions can be truly answered by a cumulative yes (or a cumulative no), still it is not a *single* answer.
48. *SE* (here referred to as part of *Top*.) $169^{a}7$–18, $175^{b}39$–$176^{a}18$, $181^{a}36$–$^{b}24$.

Among things predicated and things over which they happen to be predicated, those that are said coincidentally either about the same thing or about each other will not be one thing. For example, a human is pale and musical, but pale and musical together are not one thing, because they are both coincidents of the same thing. And even if it is true to say "pale musical," still the musical pale will not be one thing. For the musical is pale coincidentally, so the pale musical will not be one thing.[49] Nor, as a consequence, will a cobbler[50] who is unconditionally good be one thing, but an animal that is two-footed will be, for this is not coincidental. Further, all those things of which one is contained in the other will not be one thing either. That is why neither will the pale be predicated many times over nor will a human be an animal human or a two-footed human. For two-footed and animal are contained in human.

It is true to speak of the particular thing also unconditionally—for example, to call the particular human "human" and the particular pale human "pale." Not always, though. Rather, when in what is added there is contained an opposite from which a contradiction follows, it is not true but false—for example, to call a dead human "human." But when it is not contained, it is true. Or rather, when it is contained, it is always not true, while when it is not contained, it is not always true. As in this case: Homer is something, namely, a poet. Does it follow that he also is, or not? No, for "is" is predicated coincidentally of Homer. Indeed, it is because he is a poet, and not intrinsically, that "is" is predicated about Homer. So in those predications in which both no contrariety is contained when accounts are stated in place of names and the predicates are predicated intrinsically and not coincidentally, it will be true to speak of a particular case also unconditionally. It is not true that, because it is an object of belief, what is not is something that is; for the belief about it is not that it is, but that it is not.

12
Modal Affirmations and Negations

Having made these distinctions, we must investigate the mutual relations of negations and affirmations of the possible to be and the not possible, the admissible and the not admissible, and about the impossible and the necessary. For they raise certain puzzles.

For suppose we say that among composite expressions the contradictories opposed to each other are those that are ordered according to "to be" and "not to be." For example, the negation of "to be a human" is "not to be a human," not "to be a not-human"; also, the negation of "to be a pale human" is "not to be a pale human," not "to be a not-pale human" (for in that case, if either the affirmation or the negation **21b1**

49. Reading μουσικὸν ἔν τι with Weidemann.
50. Reading οὐδὲ.

applies to everything, it would be true to say that the log is a not-pale human). And if that is so, in cases in which "to be" is not added, what is said instead of "to be" will play the same role—for example, the negation of "A human walks" will not be "A not-human walks," but "A human does not walk"; for to say "A human walks" does not differ at all from saying "A human is walking." So, if this is the case everywhere, the negation of "possible to be" is "possible not to be," and not "not possible to be." Yet it seems that it is possible for the same thing both to be and not to be, because if it is possible for anything to be cut or to walk, it is also possible for it not to walk and not to be cut. The reason is that all that is possible in this way is not always actual, so the negation too will hold of it; for it is possible for what is able to walk not to walk and for what is visible not to be seen. But it is impossible for opposite phrases to be true about the same thing. Therefore, this is not the negation. For from these assumptions it follows that either it is possible to affirm and deny the same thing about the same thing at the same time, or that affirmations and negations do not come about in virtue of "to be" and "not to be" being the additional components. If, then, the former is impossible, the latter must be chosen.

The negation of "possible to be," therefore, is "not possible to be." The same account holds also for "admissible to be," for the negation of this is "not admissible to be." Likewise also in the other cases, that is, "necessary" and "impossible." For, as in the previous examples, "to be" and "not to be" are additions, while the underlying objects are pale and human, so in these cases "to be" takes the role of an underlying thing, while "to be possible" and "to be admissible" are additions, and just as "to be" and "not to be" determine the truth with regard to those underlying things, these do so with regard to being possible and being not possible.[51]

The negation of "possible not to be" is "not possible not to be." That is precisely why "possible to be" and "possible not to be" might seem to follow from each other. For it is possible for the same thing to be and not to be; for such assertions are not contradictories of each other. But "possible to be" and "not possible to be" never **22a1** hold together. For they are opposites. Nor, indeed, do "possible not to be" and "not possible not to be" ever hold together. Similarly, the negation of "necessary to be" is not "necessary not to be," but "not necessary to be"; and the negation of "necessary not to be" is "not necessary not to be." And of "impossible to be" the negation is not "impossible not to be" but "not impossible to be"; and of "impossible not to be," "not impossible not to be." And universally, as was said,[52] one must treat "to be" and "not to be" as the underlying things, and these others must be joined on to "to be" and "not to be" to make an affirmation and a negation. We must take the opposite expressions to be these: "possible" / "not possible"; "admissible" / "not admissible"; "impossible" / "not impossible"; "necessary" / "not necessary"; "true" / "not true."

51. I.e., as "is" transforms "human" and "pale" into something truth-evaluable, so "it is possible" transforms "for a human to be pale" into something truth-evaluable.
52. 21b26–32.

13
The Table of the Possible, the Admissible, the Impossible, and the Necessary

Having laid down these foundations, implications too follow along in accord with reason. From "possible to be" there follow "admissible to be" (and, conversely, the former from the latter), and "not impossible to be" and "not necessary to be." From "possible not to be" (and "admissible not to be") there follow both "not necessary not to be" and "not impossible not to be." From "not possible to be" (and "not admissible to be") there follow "necessary not to be" and "impossible to be." From "not possible not to be" (and "not admissible not to be") there follow "necessary to be" and "impossible not to be." What we say can be seen from the following table:

1	2
possible to be	not possible to be
admissible to be	not admissible to be
not impossible to be	impossible to be
not necessary to be	necessary not to be

3	4
possible not to be	not possible not to be
admissible not to be	not admissible not to be
not impossible not to be	impossible not to be
not necessary not to be	necessary to be

"Impossible" and "not impossible" follow from "admissible" and "possible" and "not admissible" and "not possible" contradictorily but conversely.[53] For the negation of "impossible" follows from "possible to be," and the affirmation from the negation; for "impossible to be" follows from "not possible to be"; for "impossible to be" is an affirmation, "not impossible" a negation.[54]

53. From the contradictory pair "possible" and "not possible" there follow "impossible" and "not impossible" as a contradictory pair ("contradictorily"), but in inverted order ("conversely"). The negative "not impossible" follows from the affirmative "possible," and the affirmative "impossible" from the negative "not possible."

54. This and the following paragraph provide a commentary on the four forms of "impossible" and of "necessary" explaining why they are arranged as they are on the table. Aristotle then raises a problem which leads to an emendation of the table.

Let us observe how it is with "necessary." Clearly not in the same way: here contraries follow[55] and contradictories are separated;[56] for "not necessary to be" is not the
22b1 negation of "necessary not to be"; for both can be true of the same thing; for what is necessary not to be is not necessary to be. The cause of their not following like the others is that, when it is equivalent to it, the impossible corresponds to the necessary
5 in a contrary way.[57] For if it is impossible to be, it is necessary for this (not, to be, but) not to be. And if it is impossible not to be, it is necessary for this to be. So if those follow from "possible" and "not possible" in the same way, these[58] follow in a contrary way, since "necessary" and "impossible" do signify the same, but, as we said, they do so conversely.

Yet perhaps it is impossible for the contradictions pertaining to the necessary to
10 be arranged in this way. For what is necessary to be is possible to be. (For otherwise the negation will follow. For it is necessary either to affirm or to deny. So if it is not possible to be, it is impossible to be. The necessary to be is thus impossible to be—which is absurd.) But[59] from "possible to be" there follows "not impossible to be"
15 and from this there follows "not necessary to be." So it follows that the necessary to be is not necessary to be—which is absurd. But again, neither "necessary to be" nor "necessary not to be" follow from "possible to be." For with the latter both outcomes can happen, but whichever of the former[60] is true, these[61] will no longer be true; for
20 it is at the same time possible to be and not to be, but if it is necessary to be or not to be, it will not be possible for both.

It remains, then, that from "possible to be" there follows "not necessary not to be," for this is also true of what is necessary to be. For this also proves to be contradictory to what follows from "not possible to be"; for it is from the latter that "impossible
25 to be" and "necessary not to be" follow, whose negation is "not necessary not to be."

---

55. According to one way of explaining this cryptic remark, in the exceptional case of necessity (last line), what follows in each quadrant is not the contradictory of what follows in the adjacent quadrant. Rather, it is the contrary of the contradictory of what correspondingly follows in the adjacent quadrant. Consider quadrant 1: the contradictory of "not necessary to be" is "necessary to be," yet what follows in quadrant 2 is the latter's contrary: "necessary not to be." It is the same in quadrants 3 and 4. However, the relation between this fact and the account that follows in the text (22b3–10) is not completely clear.

56. I.e., the expressions containing "necessary" differ from the others in not flanking their contradictory.

57. I.e., a sentence of the form "It is impossible that P" can be translated into an equivalent sentence of the form "It is necessary that not-P," and a sentence of the form "It is impossible that not-P" can be translated into an equivalent sentence of the form "It is necessary that P."

58. I.e., perhaps, all the expressions containing "necessary" (fourth lines of all quadrants). However, the examples Aristotle has just given only apply to quadrants 2 and 4. In any case, "those" refers to all the expressions containing "impossible."

59. On the basis of the table.

60. I.e., "necessary to be" and "necessary not to be."

61. I.e., "possible to be" and "possible not to be."

So these contradictories too follow in the way stated, and nothing impossible results when we put things in this way.

One might raise a puzzle as to whether "possible to be" follows from "necessary to be." For if it does not follow, its contradictory, "not possible to be," will follow. And if one were reluctant to call this "the contradictory," one would have to say that "possible not to be" is—and both are false of what is necessary to be. But then again the same thing seems capable[62] of being cut and of not being cut, of being and of not being, and, hence, what is necessary to be will be admissible not to be—but this is false. It is evident, then, that not everything capable either of being or of walking is also capable of the opposite: there are cases in which this is not true. First, with things that are capable not in accord with reason; fire, for example, is able to heat and has a non-rational capacity. So, while rational capacities[63] are the same capacities for more than one thing and for contraries, not all non-rational capacities are this way. Rather, as was said, fire is not capable of heating and of not heating, nor are all the other things that are always in activity. On the other hand, even some of the things with non-rational capacities are at the same time capable of opposites.[64] But the purpose of the point we have made is that not every capacity is for opposites—not even all those that are said to be capacities in accord with the same form. In addition, some capacities are homonymous; for things are not said to be capable in only one way. Instead, one is said to be so because it is true insofar as it is activated—for example, it is capable of walking because it is walking, and in general capable of being because it is already actively what it is said to be capable of. Another is said to be so because it might be activated—for example, capable of walking because it might walk. And this latter capacity occurs only in movable things; the former also in immovable ones. Of both it is true to say that it is not impossible to walk or to be—both of what is already walking and activated and what is able to walk. And while it is not true to attribute the second kind of capable to what is unconditionally necessary, it is true to attribute the other. So, since the universal follows from the particular,[65] "capable of being"—though not every sort of capable—follows from "being of necessity." Perhaps, indeed, the necessary and the not necessary are the starting point of everything's either being or not being, and one should investigate the others as following from these.

30 35 **23^{a}1** 5 10 15 20

It is clear from what has been said that what is of necessity *is* actively; so, if the things that always *are* are prior, then also activity is prior to capacity. Some things are activities without capacity (such as the primary substances), others with capacity (and these are prior in nature but posterior in time), and others are never activities but capacities only.[66]

14
Contrary Beliefs and Sayings[67]

Is the affirmation contrary to the negation or the affirmation to the affirmation? Is the saying that every human is just contrary to the saying "No human is just," or "Every human is just" to "Every human is unjust"? For example, "Callias is just" / "Callias is not just" / "Callias is unjust." Which of these is contrary?[68] For if voiced expressions follow things in the mind, and there the contrary belief is that of the contrary (for example, the belief that every human is just is contrary to the belief that every human is unjust), the same must also hold for voiced affirmations. If, however, it is not the case there that the belief of the contrary is contrary, neither will the affirmation be contrary to the affirmation, but rather the aforesaid negation. So we must inquire which false belief is contrary to a true belief,[69] whether the belief of the negation or the one to the effect that the contrary is the case.

I mean this: There is a true belief about the good, that it is good. Another, a false one, that it is not good, and yet another, that it is bad. Which of these two is contrary to the true one? And if they are one single belief, in accord with which of the two is it contrary? (It is false to think that contrary beliefs are defined by being of the contraries. The belief about the good, that it is good, and the belief about the bad, that it is bad, are perhaps the same, and true, whether they are one belief or more than one; yet these are contrary things. But beliefs are not contraries because they are about contraries, but rather because they are to the contrary effect.)

If, about the good, there is the belief that it is good, the belief that it is not good, and the belief that it is something else which does not and cannot hold (we must not consider as contraries any other beliefs—neither those to the effect that what does not hold holds, nor those to the effect that what holds does not hold; for there is an indefinite number of both kinds, both of those to the effect that what does not hold holds and of those to the effect that what holds does not hold—but only those in which there is deception; and this[70] is from the things from which there are generations; for generations are from opposites, so deceptions are from them too)—if, then, the good is both good and not bad, and it is the former intrinsically and the latter coincidentally (for it is coincidental to it to be not bad), but, about anything, the belief about what it is intrinsically is more true—and this holds also for the false, if indeed it holds for the true. The belief that the good is not good, then, is false of what holds intrinsically, while the belief that it is bad is false of what holds coincidentally; so the belief of the negation will be more false of the good than the

67. Several ancient and modern commentators regard this chapter as inconsistent with the distinction between contraries and contradictories advanced in Chapter 7 and have therefore doubted its authenticity.

68. I.e., which of the last two is contrary to the first?

69. Reading ψευδὴς ἀληθεῖ with Weidemann.

70. Reading αὕτη with Weidemann.

belief of the contrary. But it is the person who holds the contrary belief who is most deceived with regard to anything; for contraries are among the things that differ most with regard to the same thing. If, then, one of the two is the contrary, and the belief of the contradictory is more contrary, clearly this must be the contrary. Also, the belief that the good is bad is complex, for the same person must perhaps assume also that the good is not good.

Further, if things must be the same way also in other cases, it would seem that our account of this one has been correct too. For the belief of the contradictory[71] is the contrary either everywhere or nowhere. But in those cases where there are no contraries, the belief opposite to the true one is certainly false—for example, he who thinks that a human is not a human is deceived. If, then, these are contraries, so too are the others, those of the contradictory.

Further, the belief about the good, that it is good, and that about the not good, that it is not good, are alike; and so, in addition, are the belief about the good, that it is not good, and that about the not good, that it is good. What belief, then, is contrary to the true belief about the not good, that it is not good? Certainly not the one that says that it is bad; for this might sometimes be true at the same time, but a true belief is never contrary to a true one (for there is something not good that is bad, so that it is possible for both to be true at the same time). Nor again is it the belief that it is not bad; for these too might hold at the same time. Thus, as contrary to the belief about the not good, that it is not good, there remains the belief about the not good, that it is good. So the belief about the good too, that it is not good, is contrary to the belief about the good, that it is good.

It is evident that it will make no difference even if we regard the affirmation as universal. For the universal negation will be contrary—for example, the belief that none of the goods is good will be contrary to the belief to the effect that every good is good. For the belief about the good, that it is good, if "the good" is taken universally, is the same as the belief to the effect that whatever is good is good. And this is no different from the belief that everything which is good is good. And similarly also in the case of the not good.

So, if indeed this is how matters stand with beliefs, and voiced affirmations and negations are tokens of things in the soul, clearly what is contrary to an affirmation is the universal negation about the same thing—for example, the contrary of "Every good is good" or "Every human is good" is "No good . . ." or "No human . . ." while "Not every good . . ." or "Not every human . . ." is opposed contradictorily. It is evident also that it is not admissible either for a true belief or for a true member of a contradictory pair to be contrary to another true one. For contrary beliefs are about opposites; and while it is admissible for the same person to speak truly about them, it is not admissible for contraries to hold of the same thing at the same time.

71. Reading ἡ τῆς ἀντιφάσεως with Weidemann.

PRIOR ANALYTICS*

BOOK 1

1.1
Subject and Scope; Key Terms Defined

First, we must say what our inquiry is about and what it falls under: it is about demonstration and it falls under demonstrative science. Next, we must define what a premise is, what a term is, what a deduction is, and what sort of deduction is complete and what sort incomplete; and after these matters, what it is for something to be or not be in something as a whole, and what we mean by "to be predicated of every" or "predicated of none."

A premise, then, is a sentence that affirms or negates something of something. This sentence may be universal, particular, or indeterminate. I call belonging to every or to none "universal"; belonging to some, not to some, or not to every "particular"; and I call "indeterminate" belonging or not belonging without "universal" or "particular" (for example, "the science of contraries is the same" or "pleasure is not a good." A demonstrative premise differs from a dialectical one in that the demonstrative premise is supposing one or the other part of a contradiction (for someone who demonstrates does not ask but instead supposes), whereas a dialectical premise is the asking of a contradiction. However, this will make no difference as to whether a deduction comes about in either case; for both the one who demonstrates and the one who questions deduce by supposing something about something, either belonging or not belonging. Consequently, a deductive premise, unconditionally, will be either the affirmation or the negation of one thing about another in the way just said. It is demonstrative if it is true and has been obtained through the initial assumptions, while a dialectical premise is, for someone getting answers, the posing of a contradiction as a question, but, for someone deducing, supposing something apparent and acceptable, as was said in the *Topics*.[1] So then, what a premise is and how deductive, demonstrative, and dialectical premises differ will be stated more precisely in what follows, but let the definitions given now be sufficient for our present needs.

* Translated by Robin Smith. Text: W. D. Ross, *Aristotelis Analytica Priora et Posteriora* (Oxford, 1964; corrected, 1968).

1. *Top.* 100^{a}29–30.

I call a "term" that into which a premise is decomposed—that is, both what is predicated and that of which it is predicated (or[2] with the words "is" and[3] "is not" added to them or separating them[4]).

A deduction is an argument in which, certain things having been assumed, something different from the things assumed follows of necessity in virtue of their being so. By "in virtue of their being so," I mean "following through them," and by "following through them," I mean "needing no further term from outside in order for the necessity to come about." I call a deduction "complete" if it stands in need of nothing else besides what was supposed for the necessity to be evident; I call it "incomplete" if it still needs one or more things that are necessary through the terms assumed but have not been supposed through premises. For one thing to be in another as a whole is the same as for the latter to be predicated of all of the former. We call it "being predicated of every" when it is not possible to take anything of the subject[5] of which the other term will not be said, and "being predicated of none" likewise.

1.2
Conversions of Non-modal Premises

25[a]1 Given that every premise is one of belonging, or belonging of necessity, or being possible to belong; and of these, some are affirmative and others negative for each designation, respectively; and of the affirmative and negative premises, in turn, some are universal, some are in part, and some indeterminate—it is necessary, then, that a universal privative premise regarding belonging converts with respect to its terms. For example, if no pleasure is a good, neither will any good be a pleasure. And the positive premise necessarily converts, though not universally but in part. For example, if every pleasure is a good, some good will also be a pleasure. Among particular premises, it is necessary that the affirmative convert with respect to a part (for example, if some pleasure is a good, some good will also be a pleasure), but not necessary for the privative to (for example, it is not the case that if human does not belong to some animal, animal will also not belong to some human).

First, then, let premise AB be universal and privative. Then, if A belongs to none of the Bs, neither will B belong to any of the As.[6] For if it does belong to one (for example, to C), it will not be true that A belongs to none of the Bs;[7] for C is one

2. Reading ἢ.
3. Reading καὶ.
4. Retaining ἤ διαιρουμένου. In Greek, the words "is" or "is not" in a sentence predicating B of A may be in front of the two terms ("Is A B"), or follow them ("A B is"), or fall between ("separating") them ("A is B"), or may not occur at all ("B (the) A").
5. Retaining τοῦ ὑποκειμένου.
6. Reading οὐδενὶ τῶν B . . . οὐδὲ τῶν A οὐδενὶ.
7. Reading μηδενὶ τῶν B.

of the Bs. And if A belongs to every B, B will belong to some one of the As. For if it belongs to none, neither will A belong to any B; but it was assumed to belong to every B.

And similarly if the premise is of a part. For if A belongs to some one of the Bs, necessarily B belongs to some one of the As[8] (for if it belongs to none, neither will A belong to any of the Bs[9]). But if A does not belong to some one of the Bs, it is not necessary that B also not belong to some one of the As (for example, if B is animal and A human: human does not belong to every animal, but animal belongs to every human).

1.3
Conversions of Necessary and Possible Premises

It will be the same way in the case of necessary premises: that is, the universal privative premise converts universally, while each sort of affirmative premise converts in respect of a part. For if it is necessary that A belongs to none of the Bs, it is necessary that B belongs to none of the As (for if it is possible that it belongs to some, it would also be possible that A belongs to some B). And if A belongs to all or some one of the Bs of necessity, it is necessary that B belong to some A (for if it is not necessary, neither would A belong to some B of necessity). But the privative particular does not convert, due to the same cause as we said previously.

In the case of possible premises, since things are said to be possible in many ways—for we say that what is necessary is possible, and also that what is not necessary is, and also that what is potential is—the situation with respect to conversion will be the same in all these cases with the affirmatives. For if it is possible for A to belong to every or to some B, it will also be possible for B to belong to some A: for if it is not possible for it to belong to any, neither will it be possible for A to belong to any B (this was proved previously[10]).

But it is not the same way with negative premises, although it is the same for those said to be possible because they of necessity do not[11] belong or do not of necessity belong—for example, if someone should say that it is possible that a human is not a horse or that white belongs to no cloak. For the first of these of necessity does not belong, while the second does not necessarily belong, and the premise converts similarly. For if it is possible that horse belongs to no human, it is possible that human belongs to no horse; and if it is possible that white belongs to no cloak, it is possible that cloak belongs to no white. For if it is necessary to some, white will also belong

8. Reading τινὶ τῶν B . . . τινὶ τῶν A.
9. Reading οὐδενὶ τῶν B.
10. $25^{a}29–32$.
11. Reading τῷ ἐξ ἀνάγκης μὴ ὑπάρχειν ἢ τῷ μὴ ἐξ ἀνάγκης ὑπάρχειν.

of necessity to some cloak (this was proved previously[12]). It is the same way with the negative particular premise.

But what is said to be possible because of being so for the most part or being naturally so (which is the way that we define possible) will not be in the same relationship in privative conversions; instead, the universal privative premise does not convert and the particular premise does.

This will be evident when we discuss the possible. For the present, however, let this much be clear in addition to what has been said: that "is possible to belong to none" or "is possible not to belong to some" is affirmative in form. For "is possible" is ordered in the same way as "is," and "is" always and in all ways makes what it is added to in predication an affirmation, as in "is not-good" or "is not-white," or simply "is not-this" (this too will be proved in what follows[13]); and with respect to their conversions, they will be in the same relationship as the others.

1.4
Deductions in the First Figure

Having made these distinctions, let us proceed to say through what, when, and how every deduction comes about. (Demonstration will need to be discussed later. Deduction must be discussed before demonstration because deduction is more universal: a demonstration is a sort of deduction, but not every deduction is a demonstration.)

Whenever, then, three terms are so related to each other that the last is in the middle as a whole and the middle is either in the first as a whole or not in it as a whole, there is necessarily a complete deduction of the extreme terms. (I call that term the "middle" which both is itself in another and has another in it—this is also middle in position—and call both what is itself in another and what has another in it "extremes.") For if A is predicated of every B and B of every C, necessarily A is predicated of every C (for it was said earlier what we mean by "of every"[14]). Similarly, if A is predicated of no B and B of every C, it is necessary that A will belong to no C. But if the first term follows all the middle and the middle belongs to none of the last, there will not be a deduction of the extremes; for nothing necessary results in virtue of these things being so. For it is possible for the first extreme to belong to all as well as to none of the last, so that neither a particular nor a universal conclusion becomes necessary; and, since nothing is necessary because of these, there will not be a deduction. Terms for belonging to every are animal, human, horse; for belonging to none, animal, human, stone. Nor when the first term belongs to no middle and the middle term to no last: there will not be a deduction this way either. Terms for belonging are science, line, medicine; for not belonging, science, line, unit.

12. 25ᵃ32–34.
13. 32ᵃ29–ᵇ3; cf. 1.46.
14. 24ᵇ26–30.

When the terms are universal, then, it is clear when there will and when there will not be a deduction in this figure. And it is also clear both that if there is a deduction, the terms must necessarily be related as we have said, and that if they are related in this way, there will be a deduction.

If one of the terms is universal and the other particular in relation to the remaining term, then when the universal is put with the major extreme (whether it is positive or privative) and the particular is put with the positive minor extreme, there will necessarily be a complete deduction, but when the universal is supposed in relation to the minor extreme, or when the terms are related in any other way, this is impossible. (I call that extreme the "major" which the middle is in and that extreme the "minor" which is under the middle.) For let A belong to every B and B to some C. Then if "to be predicated of every" means what was said at the start, it is necessary that A belongs to some C. And if A belongs to no B and B to some C, it is necessary that A does not belong to some C—for what we mean by "predicated of no" has been defined—so that there will be a complete deduction. And similarly if BC is indeterminate while being positive (for it will be the same deduction whether an indeterminate or a particular premise is supposed).

But if the universal is put with the minor extreme (whether positive or privative), there will not be a deduction either when the indeterminate or particular is affirmative or when it is negative (that is, if A belongs or does not belong to some B and B belongs to every C). Terms for belonging are good, state, practical wisdom; terms for not belonging are good, state, ignorance. Next, if B belongs to no C and A belongs or does not belong to some B, or does not belong to every B, there will not be a deduction in this way either. Terms are white, horse, swan; white, horse, raven. And the same terms also if AB is indeterminate.

Nor will there be a deduction when the term related to the major extreme is universally either positive or privative and the term related to the minor is privative and particular, whether this is supposed as indefinite or as particular[15] (for example, if A belongs to every B and B does not belong to some C, or if it does not belong to every C). For whatever part [of the last extreme] the middle does not belong to, the first extreme can follow both all and none of that. For let the terms animal, human, and white be assumed, and next, from among those white things human is not predicated of, let swan and snow be selected. Then, animal is predicated of all of one but of none of the other, so that there will not be a deduction.

Again, let A belong to no B and B not belong to some C, and let the terms be inanimate, human, white. Next, let swan and snow be selected from among those white things human is not predicated of (for inanimate is predicated of all of one and none of the other). In addition, since "B does not belong to some C" is indeterminate and is a true statement if B belongs to none as well as if it does not belong to all (because it does not belong to some), and since a deduction does not come about

15. Retaining ἀδιορίστου τε καὶ ἐν μέρει ληφθέντος.

when terms are supposed such that B belongs to none (this was said previously[16]), it is evident that there will not be a deduction through the terms being in this relationship either (for there would also have been one for those terms). It may be proved similarly if the universal is put as privative.

Nor will there be a deduction in any way if both the intervals[17] are particular, whether they are said positively, or privatively, or one positively and the other privatively, or one is indeterminate and the other determinate, or both are indeterminate. Common terms for them all are animal, white, horse; animal, white, stone.

It is evident from what has been said, then, that if there is a particular deduction in this figure, it is necessary for the terms to be related as we have said; for when they are related otherwise, in no way does a deduction come about. It is also clear that all the deductions in it are complete (for they are all brought to completion through the premises initially supposed), and that all the problems[18] are proved through this figure (that is, belonging to every, to none, to some, and not to some). I call this sort of figure the "first."

1.5
Deductions in the Second Figure

When the same thing belongs to all of one term and to none of the other, or to all of each or none of each, I call such a figure the "second." In it, I call that term the "middle" which is predicated of both and call those of which this is predicated "extremes"; the "major" extreme is the one placed next to the middle, and the "minor" extreme is the one further from the middle. The middle is placed outside the extremes and is **27ᵃ1** first in position. There cannot be a complete deduction in this figure in any way, but there can be a potential[19] one, both when the terms are universal and when they are not universal.

When the terms are universal, there will be a deduction when the middle belongs to all of one term and none of the other, no matter which term the privative is put with, but otherwise in no way. For let M be predicated of no N but of every X. Then, since the privative converts, N will belong to no M. But M was assumed to belong to every X, so that N belongs to no X (for this has been proved previously[20]). Next, if M belongs to every N but to no X, neither will X belong to any N. For if M belongs to no X, neither does X belong to any M; but M belonged to every N; therefore, X will belong to no N (for the first figure has again come about). And since the privative converts, neither will N belong to any X, so that there will be the same deduction.

16. 26ᵃ9–13.
17. I.e., premises.
18. I.e., sorts of conclusions.
19. I.e., incomplete.
20. 27ᵃ5–8.

(It is also possible to prove these results by reducing to the impossible.) It is therefore evident that a deduction comes about when the terms are related in this way, but it is not complete; for the necessary result is brought to completion, not from the initial premises alone, but from others in addition.

But if M is predicated of every N and of every X, there will not be a deduction. Terms for belonging are substance, animal, human; for not belonging, substance, animal, number (the middle is substance). Nor when M is predicated neither of any N nor of any X. Terms for belonging are line, animal, human; for not belonging, line, animal, stone.

It is evident, then, that if there is a deduction when the terms are universal, it is necessary for the terms to be related as we said at the start; for if they are otherwise, a necessary result does not come about.

If the middle is universal only in relation to one term, when it is universal in relation to the major extreme (whether positively or privatively) but particular in relation to the minor and oppositely to the universal (by "oppositely" I mean that if the universal is privative, then the particular is affirmative, while if the universal is positive the particular is privative), it is necessary for a privative particular deduction to come about. For if M belongs to no N and to some X, it is necessary that N does not belong to some X. For since the privative converts, N will not belong to any M; but M was assumed to belong to some X; consequently, N will not belong to some X, for a deduction through the first figure comes about. Next, if M belongs to every N but does not belong to some X, it is necessary for N not to belong to some X. For if it belongs to every X and M is also predicated of every N, it is necessary for M to belong to every X, but it was assumed not to belong to some. And if M belongs to every N but not to every X, there will be a deduction that N does not belong to every X. (The demonstration is the same.) But if it is predicated of every X and not of every N, there will not be a deduction (terms are animal, substance, raven; animal, white, raven). Nor will there be one when it is predicated of no X but of some N (terms for belonging are animal, substance, unit; for not belonging, animal, substance, science).

When the universal premise is opposite to the particular, then, it has been said when there will and when there will not be a deduction. But when the premises are the same in form (that is, both are privative or both affirmative), in no way will there be a deduction. For let the premises first be privative, and let the universal be put with the major extreme (that is, let M belong to no N and not to some X). It is then possible for N to belong to every X as well as to none. Terms for not belonging are black, snow, animal. We cannot get terms for belonging if M belongs to some X and does not belong to some. For if N belongs to every X and M to no N, M will belong to no X: but it was assumed to belong to some. We cannot get terms in this way, then, and it must be proved from the indeterminate. For since "M does not belong to some X" is also true even if M belongs to no X and there was not a deduction when it belonged to none, it is evident that there will not be one in the present case either.

Next, let the premises be positive, and let the universal be supposed in the same way as the particular (that is, let M belong to every N and to some X). It is then possible for N to belong to every X as well as to none. Terms for belonging to none are white, swan, stone, but we will not be able to get terms for belonging to every due to the same cause as previously; it must instead be proved from the indeterminate. And if the universal is by the minor extreme (that is, M belongs to no X and does not belong to some N), it is possible for N to belong to every X as well as to none. Terms for belonging are white, animal, raven; for not belonging, white, stone, raven. If the premises are positive, terms for not belonging are white, animal, snow; for belonging, white, animal, raven.

It is evident, then, that when the premises are the same in form, and one is universal and one particular, a deduction does not come about in any way. And neither does it if the middle term belongs or does not belong to some of each extreme, or belongs to one and does not belong to the other, or not to all of either, or indeterminately. Common terms for all these are white, animal, human; white, animal, inanimate.

From what has been said, then, it is evident both that if the terms are related to each other as was said, a deduction comes about of necessity and that if there is a deduction, it is necessary for the terms to be so related. It is also clear both that all the deductions in this figure are incomplete (for they are all brought to completion by taking in addition certain things which either are implicit in the terms of necessity or are supposed as assumptions, as when we prove through an impossibility) and that an affirmative deduction does not come about through this figure, but rather all the deductions, universal as well as particular, are privative.

1.6
Deductions in the Third Figure

If one term belongs to all and another to none of the same thing, or if they both belong to all or none of it, I call such a figure the "third." By the "middle" in it I mean that term of which they are both predicated, and by "extremes" the things predicated: by "major" extreme I mean the one farther from the middle and by "minor" the one closer. The middle is placed outside the extremes and is last in position. A complete deduction does not come about in this figure either, then, but a potential one may, both when the terms are universal and when they are not universal in relation to the middle.

With universal terms, then, when both P and R belong to every S, it follows of necessity that P will belong to some R. For since the positive premise converts, S will belong to some R; consequently, since P belongs to every S and S to some R, it is necessary that P belongs to some R; for it becomes a deduction through the first figure. It is also possible to carry out the demonstration through the impossible and through the setting-out. For if both terms belong to every S, if some one of the Ss

is selected (for example, N), both P and R will belong to this; consequently, P will belong to some R.

And if R belongs to every S but P to none, there will be a deduction that P of necessity does not belong to some R (for the way of demonstrating it is the same if premise RS is converted). It could also be proved through the impossible as in the previous cases. But if R belongs to no S and P belongs to every S, there will not be a deduction (terms for belonging are animal, horse, human; for not belonging, animal, inanimate, human). Nor will there be a deduction when both are said of no S (terms for belonging are animal, horse, inanimate; for not belonging, human, horse, inanimate; the middle is inanimate).

It is therefore evident when there will and when there will not be a deduction with universal terms in this figure. For when both terms are positive, there will be a deduction that one extreme belongs to some of the other extreme, but when they are privative there will not be. And when one term is privative and the other affirmative, if the major term is privative and the other term affirmative, there will be a deduction **28^b1** that one extreme does not belong to some of the other, but if it is the other way around, there will not be one.

If one term is universal in relation to the middle and the other term is particular, when both terms are positive it is necessary for a deduction to come about, no matter which of the terms is universal. For if R belongs to every S and P to some S, it is necessary that P belongs to some R. For since the affirmative converts, S will belong to some P; consequently, since R belongs to every S and S to some P, R will also belong to some P, and consequently P to some R. Next, if R belongs to some S and P to every S, it is necessary that P belongs to some R (for it is demonstrated in the same way). It can also be demonstrated through the impossible or by means of the setting-out, as in the previous cases.

But if one term is positive, the other privative, and the positive term is universal, when the minor term is positive, there will be a deduction. For if R belongs to every S and P does not belong to some, it is necessary that P does not belong to some R. For if it belongs to every R and R to every S, P will also belong to every S; but it did not belong. (This can also be proved without reduction if some one of the Ss is taken to which P does not belong.) But when the major term is positive (for example, if P belongs to every S and R does not belong to some S), there will not be a deduction. Terms for belonging to every are animate, human, animal. We cannot get terms for belonging to none, if R belongs to some S and does not belong to some S (for if P belongs to every S and R to some S, P will belong to some R, but it was assumed to belong to none). We must rather take it as in the previous cases, that is, since "does not belong to some" is indeterminate it is true to say that what belongs to none does not belong to some, and when it belonged to none there was not a deduction. It is therefore evident that there will not be a deduction.

If the privative term is universal, when the major term is privative and the minor positive, there can be a deduction. For if P belongs to no S and R belongs to some S,

P will not belong to some R; for it will be the first figure again when premise RS is converted. But when the minor term is privative, there will not be a deduction (terms for belonging are animal, human, wild; for not belonging, animal, science, wild; the middle in both is wild). Nor can there be a deduction when both terms are put as privative but one is universal and the other particular. Terms for the case when the minor extreme is universal in relation to the middle are animal, science, wild; animal, human, wild. When the major extreme is universal, terms for not belonging are raven, snow, white. We cannot get terms for belonging if R belongs to some S and does not belong to some: for if P belongs to every R and R to some S, P will also belong to some S, but it was assumed to belong to none. Instead, it must be proved from the indeterminate.

Nor will there be a deduction in any way if each term belongs or does not belong to some of the middle, or if one belongs and the other does not belong, or if one belongs to some and the other not to every, or if they belong indeterminately. Common terms for all these are animal, human, white; animal, inanimate, white.

Therefore, it is also evident when there will and when there will not be a deduction in this figure, and [it is evident] both that if the terms are related as was said, a deduction comes about of necessity, and that if there is a deduction, it is necessary for the terms to be so related. It is also evident that all the deductions in this figure are incomplete (for all are completed by taking certain things in addition) and that it is not possible to deduce a universal conclusion, whether privative or affirmative, through this figure.

1.7
More on Deductions; All Deductions Reduce to the First Figure

It is also clear that in all the figures, whenever a deduction does not come about, if both the terms are positive or privative no necessary result comes about at all, but if one term is positive and the other privative, when the privative is taken as universal, a deduction of the minor extreme in relation to the major always comes about. For example, if A belongs to every or to some B and B to no C: when the premises are converted, it is necessary that C does not belong to some A. And similarly in the case of the other figures, for a deduction always comes about through conversion. It is also clear that putting an indeterminate premise in place of a positive particular will produce the same deduction in all the figures.

It is furthermore evident that all the incomplete deductions are completed through the first figure. For they all come to a conclusion either probatively or through the impossible, and in both ways it becomes the first figure. With those completed probatively, that is because they all come to a conclusion through conversion, and conversion produces the first figure. For those proved through the impossible, this is because, when a falsehood is supposed, the deduction comes about through the first

figure. For example, it is proved in the last figure that if both A and B belong to every C, A will belong to some B: for if it belongs to none and B to every C, A will belong to no C: but it belonged to every C. And similarly also in the other cases.

It is also possible to reduce all deductions to the universal deductions in the first **29^b1** figure. It is evident that those in the second figure are completed through these deductions, although not all in the same way: the universal deductions are completed when the privative premise is converted, but each of the particular deductions is completed through reducing to the impossible. As for the deductions in the first 5 figure, the particular ones are indeed brought to completion through themselves, but it is also possible to prove them through the second figure by reducing to the impossible. For example, if A belongs to every B and B to some C, we can prove that A belongs to some C. For if it belongs to no C and to every B, B will not belong to any C (for we know this through the second figure). The demonstration will also 10 proceed similarly in the case of the privative deduction. For if A belongs to no B and B to some C, A will not belong to some C. For if it belongs to every C, but to no B, neither will B belong to any C (this was the middle figure). Consequently, since the deductions in the middle figure are all reduced to the universal deductions in the 15 first, while the particular deductions in the first figure are reduced to the deductions in the middle figure, it is evident that the particular deductions can also be reduced to the universal deductions in the first figure. The deductions in the third figure are brought to completion directly through those [in the first figure] when their terms are universal and through the particular deductions in the first figure when their terms 20 are taken as particular. But the latter were reduced to the former, and so the particular deductions in the third figure are also reduced to them. It is evident, then, that they all can be reduced to the universal deductions in the first figure. 25

It has been said, then, how those deductions that prove something to belong or not to belong are related: both how those from the same figure are related among themselves, and how those from different figures are related to each other.

1.8
Deductions with Two Necessary Premises

Since to belong, to belong of necessity, and to be possible to belong are distinct (for 30 many things belong, but nonetheless not of necessity, while others neither belong of necessity nor belong at all, but it is possible for them to belong), it is clear that there will also be distinct deductions of each and that their terms will not be alike: instead, one deduction will be from necessary terms, one from belonging terms, and one from possible terms. 35

In the case of necessary premises, then, the situation is almost the same as with premises of belonging: that is, when the terms are put in the same way both in the case of belonging and in the case of belonging or not belonging of necessity, there

will likewise either be or not be a deduction (except that these will differ by adding
30ᵃ1 "belonging (or not belonging) of necessity" to the terms). For the privative premise converts in the same way, and we will define "being in as a whole" and "predicated of every" in the same way.

In the other cases, then, the necessary conclusion will be proved through conversion in the same way as in the case of belonging. But in the middle figure, when the universal is affirmative and the particular is privative, and again in the third, when the universal is positive and the particular privative, the demonstration is not possible in the same way, and instead it is necessary to set-out that part to which each term does not belong and construct the deduction about this. For [the term] will be necessary of [each of] these; and if it is necessary of what is set-out, it will be necessary of some part of that former term (for what is set-out is precisely a certain *that*). Each of these deductions occurs in its own figure.

1.9
Deductions with One Necessary Premise in the First Figure

It sometimes happens that the deduction is necessary when only one of the premises is necessary—not, however, whatever premise one likes, but only the premise directed to the major extreme. For example, if A has been taken to belong or not to belong of necessity to B, and B only to belong to C. For if the premises have been taken in this way, A will belong or not belong to C of necessity. For since A belongs or does not belong of necessity to every B and C is some one of the Bs, it is evident that one or the other of these will also apply to C of necessity.

However, if AB is not necessary but BC is necessary, the conclusion will not be necessary. For if it is, that A belongs of necessity to some B will result both through the first and through the third figure. But this is false: for it is possible for B to be the sort of thing that it is possible A belongs to none of. It is in addition evident from terms that the conclusion can fail to be necessary, as, for example, if A is movement, B animal, and C stands for human. For a human is of necessity an animal, but an animal does not move of necessity, nor does a human. It would also be similar if AB were privative (for the demonstration is the same).

In the case of particular deductions, if the universal is necessary, the conclusion will also be necessary, but if the particular is, the conclusion will not be necessary either when the universal premise is privative or when it is positive. First, then, let the universal be necessary, and let A belong to every B of necessity, but let B only belong to some C. Then it is necessary for A to belong to some C of necessity (for C is below B, and A belonged to every B of necessity). It will also be this way if the deduction
30ᵇ1 is privative; for the demonstration will be the same. But if the particular is necessary, the conclusion will not be necessary (for nothing impossible happens), as it was also

in the case of universal deductions. And similarly in the case of the privatives. Terms are movement, animal, white.

1.10
Deductions with One Necessary Premise in the Second Figure

In the case of the second figure, if the privative premise is necessary, the conclusion will also be necessary, but if the positive premise is, the conclusion will not be necessary. For first let the privative be necessary, and let it not be possible that A belongs to any B, but let A merely belong to C. Then, since the privative converts, neither is it possible for B to belong to any A. But A belongs to every C, so that it is not possible for B to belong to any C (for C is below A). And likewise also, if the privative is put with C. For if it is not possible for A to belong to any C, neither will it be possible for C to belong to any A. But A belongs to every B; consequently, it will not be possible for C to belong to any of the Bs;[21] for it becomes the first figure again. Therefore, neither will it be possible for B to belong to C, for it converts similarly.

But if the positive premise is necessary, the conclusion will not be necessary. For let A belong to every B of necessity but merely belong to no C. Then when the privative premise is converted, it becomes the first figure, and it was proved[22] that in the first figure, when a privative premise that is related to the major term is not necessary, the conclusion will not be necessary either. Consequently, neither will it be of necessity in this case. Moreover, if the conclusion is necessary, it follows that C of necessity does not belong to some A. For if B belongs of necessity to no C, C will also belong of necessity to no B. But it would be necessary for B to belong to some A, if indeed A belonged to every B of necessity. Consequently, it would be necessary for C not to belong to some A. But nothing prevents something having been taken as A to all of which it is possible that C belongs. Moreover, it would be possible to prove by setting-out terms that the conclusion is not unconditionally necessary but only necessary when these things are so. For example, let A be animal, B human, C white, and let the premises have been taken in the same way. So it is possible that animal belongs to nothing white. Human will then indeed not belong to anything white either, but not of necessity; for it is possible for a human to become white, although not while animal belongs to nothing white. Consequently, the conclusion will be necessary when these things are so, but not unconditionally necessary.

It will be the same in the case of the particular deductions. For when the privative premise is both universal and necessary, the conclusion will also be necessary; but when the positive premise is universal and the negative premise is particular, the conclusion will not be necessary. First, then, let the privative premise be both

21. Reading οὐδενὶ τῶν B.
22. 30^a23–32.

universal and necessary: and let it not be possible that A belongs to any B, but let it belong to some C. Then, since the privative converts, neither will it be possible that B belongs to any A. But A belongs to some one of the Cs, so that B will of necessity not belong to some one of the Cs.[23] Next, let the positive premise be both universal and necessary, and let the positive be put with B. So if A belongs to every B of necessity, but does not belong to some C, it is evident that B will not belong to some C, but not of necessity. (For the same terms will serve for the demonstration as in the case of the universal deductions.) But neither will the conclusion be necessary if the privative, taken as particular, is necessary (for the demonstration is through the same terms).

1.11
Deductions with One Necessary Premise in the Third Figure

In the last figure, if the terms are universal in relation to the middle and both the premises are positive, then if either one is necessary the conclusion will also be necessary. However, if one is privative and the other positive, then when the negative is necessary the conclusion will also be necessary, but when the positive is necessary the conclusion will not be necessary. For let both premises first be positive, and let both A and B belong to every C, but let AC be necessary. Then, since B belongs to every C, C will also belong to some B (because the universal converts into a particular). Consequently, if A belongs to every C of necessity and C belongs to some B, it is also necessary for A to belong to some B (for B is under C). It becomes the first figure, then. And it will also be proved in the same way if BC is necessary. For C converts to some A, so that if B belongs to every C of necessity, it will also belong to some A of necessity.

Next, let AC be privative, BC affirmative, and the privative necessary. Then, since C converts to some B and A belongs of necessity to no C, A will also of necessity not belong to some B (for B is below C). But if the positive premise is necessary, the conclusion will not be necessary. For let BC be positive and necessary and AC privative and not necessary. Then, since the affirmative converts, C will belong to some one of the Bs[24] of necessity. Consequently, if A belongs to no C and C to some one of the Bs,[25] A will not belong to some one of the Bs, but not of necessity: for it was proved[26] in the first figure that when the privative premise is not necessary, the conclusion will not be necessary either. This could also be evident through terms. For let A be good, B stand for animal, and C horse. Then it is possible that good belongs to no horse and necessary that animal belongs to every horse, but it is not necessary for some animal not to be good, if indeed it is possible for every one to be good. (Or

23. Reading τινὶ τῶν Γ . . . τινὶ τῶν Γ.
24. Reading τινὶ τῶν Β.
25. Reading τινὶ τῶν Β . . . τινὶ τῶν Β.
26. 30a23–32, 30b2–6.

if this is not possible, being awake or sleeping should be put as a term instead, for every animal is receptive of these.)

It has been said, then, when the conclusion will be necessary if the terms are universal in relation to the middle. But if one term is universal, the other is particular, and both are positive, the conclusion will be necessary whenever the universal is necessary. The demonstration is the same as the previous one; for the positive particular also converts. Thus, if it is necessary for B to belong to every C and A is below C, it is necessary for B to belong to some A. But if it is necessary for B to belong to some A, it is also necessary for A to belong to some B (for it converts). It would also be similar if AC were necessary and universal (for B is below C).

If the particular premise is necessary, the conclusion will not be necessary. For let BC be both particular and necessary. And let A belong to every C, however not of necessity. Then, when BC is converted, it becomes the first figure, and the universal premise is not necessary while the particular premise is necessary. But when the premises were like this, the conclusion was not necessary; consequently, it will not be in this case either. Moreover, this is also evident from terms. For let A be wakefulness, B something two-footed, and C stand for animal. Then, it is necessary that B belongs to some C, it is possible that A belongs to C, and it is not necessary for A to belong to B (for it is not necessary for something two-footed to be asleep or awake). It can also be proved in the same way, through the same terms, if AC is both particular and necessary.

But if one of the terms is positive and the other privative, when the universal is both privative and necessary, the conclusion will also be necessary. For if it is not possible for A to belong to any C, and B belongs to some C, it is necessary that A does not belong to some B. But when the affirmative is put as necessary (whether it is universal or particular), or when the privative is particular, the conclusion will not be necessary. The proofs for the rest are the same as those we said concerning the previous cases; terms for the case in which the necessary positive premise is universal are wakefulness, animal, human (with human the middle); when the positive necessary premise is particular, they are wakefulness, animal, white. For it is necessary **32^a1** that animal belongs to something white, but it is possible that wakefulness belongs to nothing white, and it is not necessary that wakefulness does not belong to some animal. When the privative is particular and necessary, the terms are two-footed, moving, animal (with animal the middle).

1.12
Some Results about Deductions with Necessary Premises

It is evident, then, that there is no deduction of belonging unless both the premises express belonging; a deduction of belonging of necessity is possible, however, even when only one premise is necessary. But in both cases, with either affirmative or

privative deductions, it is necessary for one or the other premise to be like the conclusion. By "like" I mean that if the conclusion is belonging, the premise must be belonging, and if the conclusion is necessary, the premise must be necessary. Consequently, this also is clear, that the conclusion cannot be either necessary or belonging unless a necessary or a belonging premise has been taken.

1.13
Conversion of Possible Premises; Definition of Possible

About enough has been said, then, concerning what is necessary, how it comes about, and what differentiates it in relation to what belongs. After this, let us say when, and how, and through what premises there can be a deduction of what is possible. I use the expressions "to be possible" and "what is possible" of whatever is not necessary but, when it is supposed to be the case, nothing will be impossible because of this (for we say that what is necessary is possible homonymously). {It is evident that this is what "possible" is from opposed pairs of negations and affirmations. For "it is not possible to belong" and "it is impossible to belong" and "it is necessary not to belong" are either the same or follow each other, and so their opposites "it is possible to belong," "it is not impossible to belong," and "it is not necessary not to belong" will also either be the same or follow from each other (for either the affirmation or the negation is [true] of everything). Therefore, what is possible will not be necessary and what is not necessary will be possible.}[27]

It follows that all premises about being possible convert with each other. I do not mean that affirmative premises convert with negatives, but rather that such as have an affirmative form convert with respect to their opposite: that is, "possible to belong" converts to "possible not to belong," "possible to belong to every" converts to "possible to belong to no" (or "not to every"), and "it is possible to belong to some" converts to "it is possible not to belong to some." It is also the same way for the others. For since what is possible is not necessary, and it is possible for what is not necessary not to belong, it is evident that, if it is possible for A to belong to B, it is also possible for it not to belong; and, if it is possible for it to belong to every one, it is also possible for it not to belong to every one. And it will also be the same in the case of particular affirmations (for the demonstration is the same). Such premises as these are positive and not privative: for "to be possible" is ordered in the same way as "to be," as was said previously.[28]

Having made these distinctions, let us say next that things are said to be possible in two ways. One is what happens for the most part and falls short of necessity, as for a human to turn gray or grow or shrink, or, in general, for what is natural to belong

27. Rejected as an inauthentic later addition by most editors, because of its apparent inconsistency with the definition of "possible."
28. 25b19–25.

(for this does not have continuous necessity because a human does not always exist; however, when a human does exist, it happens either of necessity or for the most part). The other is the indefinite, that which is capable of being thus as well as not thus, as for an animal to walk or for there to be an earthquake while one is walking, or, in general, what comes about by luck (for it is no more natural for this to happen in one way than in the contrary way). Each of these sorts of possible premise converts with its opposite premise, although not in the same way. A premise about what is natural converts because it does not belong of necessity (for it is in this way that it is possible for a human not to turn gray), whereas a premise about what is indefinite converts because it is no more this way than that. Science—that is, demonstrative deduction—is not possible concerning the indefinite because the middle term is disorderly, but it is possible concerning what is natural, and arguments and inquiries pretty much arise about what is possible in this way. A deduction could perhaps arise about the former, but that is at any rate not usually sought for.

These matters will be better determined in what follows, but for the present let us say when and how there can be a deduction from possible premises, and what it will be. The expression "it is possible for this to belong to that" may be understood in two ways: it may mean either "to that to which this belongs" or "to that to which it is possible that this belongs." (For "A is possible of that of which B" signifies one or the other of the following: "of which B is said" or "of which it is possible that B is said." But "A is possible of that of which B" is no different from "it is possible that A belongs to every B".) Therefore, it is evident that "it is possible that A belongs to every B" may be said in two ways. So, let us first say what deduction and what sort of deduction there will be if the premises are that B is possible of what C is, and A is possible of what B is. {For in this way both premises are supposed as expressing being possible, but when the premise is that A is possible of that of which B is the case, one premise is belonging and the other is possible.}[29] So we should begin from premises that are the same in form, as also in the other cases.

1.14
Deductions with Two Possible Premises in the First Figure

When it is possible that A belongs to every B and B to every C, there will be a complete deduction that it is possible that A belongs to every C. This is evident from the definition (for this is how we meant "to be possible to belong to every"). And similarly, if it is possible that A belongs to no B and B to every C, there will be a complete deduction that A is possible to no C (since "A is not possible of that of which B is possible" meant precisely this: not leaving out anything that is possibly under B). When A is possible to every B and B is possible to no C, no deduction comes about

29. Some editors reject this sentence as a later addition.

through the premises taken, but if premise BC is converted in accord with possibility, it becomes the same deduction as before. For since it is possible that B belongs to no C, it is also possible that it belongs to every C (this was said previously[30]). So, if B belongs to every C and A to every B, the same deduction comes about again.

Similarly, if to both premises a negation is added along with "is possible" (I mean, for example, if A is possible to none of the Bs and B to none of the Cs[31]). For no deduction comes about through the premises taken, but if they are converted it will again be the same deduction as previously.

It is evident, then, that when a negation is added to the minor extreme or to both premises, either no deduction comes about, or one does come about but it is not complete (for the necessity is concluded from conversion).

But if one of the premises is taken as universal and the other as particular, when the universal premise is the one related to the major extreme there will be a complete[32] deduction. For if A is possible to every B and B to some one of the Cs, A is possible to some C (this is evident from the definition of "to be possible"). Next, if it is possible that A belongs to no B and B belongs to some C, it is necessary that it is possible for A not to belong to some one of the Cs (the demonstration is the same).

But if the particular premise is taken as privative, the universal premise as affirmative, and they are similarly positioned—that is, it is possible that A belongs to every B and possible that B does not belong to some C—then an evident deduction does not come about through the premises taken, but when the particular premise is converted and it is supposed that it is possible that B belongs to some C, there will be the same conclusion as previously, as in the initial cases.

If the premise with the major extreme is taken as particular and the premise related to the minor as universal, then whether both are put as affirmatives, or both as privatives, or they are not put as the same in form, or both as indeterminates or particulars, there will not be a deduction in any way. For nothing prevents B from extending beyond A and not being predicated of equally many things. Suppose that C is that by which B extends beyond A: it will not be possible for A to belong to all of this, or to none, or to some, or not to some, since premises according to possibility convert and it is possible for B to belong to more things than A does. Moreover, this is evident from terms. For with premises like these, it is not possible for the first term to belong to any of the last and also necessary that the first belongs to all of the last. Terms in common for all cases, for belonging of necessity, are animal, white, human; for not being possible, animal, white, cloak. Since there exist terms in this relationship, then, it is evident that no deduction comes about. For every deduction is of belonging, or of belonging of necessity, or of being possible. It is evident, then, that there is not a deduction of belonging or of belonging necessarily, for the affirmative

30. 32a29–b1.
31. Reading μηδενὶ τῶν Β . . . μηδενὶ τῶν Γ.
32. Retaining τέλειος.

deduction is ruled out by the privative conclusion and the privative deduction by the affirmative conclusion. So, what is left is a deduction of being possible. But this is impossible, for it has been proved[33] that with terms so related, it can be necessary for the first to belong to all the last, as well as not possible for the first to belong to any of the last. Thus, there will not be a deduction of being possible (for what is necessary was not possible).

It is evident, then, that when the terms are universal in possible premises, a deduction always comes about in the first figure, both when the terms are positive and when they are privative (except that when they are positive it is complete, while when they are privative it is incomplete). "To be possible" must be taken not in the sense that applies to what is necessary, but rather according to the determination stated (this is sometimes overlooked).

1.15
First Figure: One Possible and One Non-modal Premise

If one of the premises is supposed as belonging and the other as possible, then when the premise related to the major extreme signifies being possible, all the deductions will be both complete and of being possible according to the definition stated. However, when the premise related to the minor extreme does, not only are the deductions all incomplete, but also the privative deductions among them are not of what is possible according to the definition but rather of what belongs of necessity to none or not to every (for if something belongs of necessity to none, or not to every, we do also say that it is possible that it belongs to none or not to every). For let A be possible to every B and let B be put as belonging to every C. Then, since C is below B and A is possible to every B, it is evident that it is also possible for A to belong to every C. Thus, a complete deduction comes about. And similarly, if premise AB is privative, premise BC is affirmative, and one premise is taken as possible while the other is taken as belonging, there will be a complete deduction that it is possible for A to belong to no C.

It is evident, then, that when belonging is put with the minor extreme, complete deductions come about. But that there will be deductions when it is contrariwise must be proved through the impossible (and it will be clear at the same time that they are incomplete, for the proof is not from the premises taken).

It must first be said that if it is necessary that B is when A is, then when A is possible[34] B will of necessity also be possible. For with the terms like this, let what A stands for be possible and what B stands for be impossible. Then, if what is possible, when it is possible for it to be, could come about, and what is impossible, when

33. With the example terms in this same argument.

34. *Dunaton*, which can also mean "potential" (25^a37–40), is used in 34^a5–33 in place of *endechomenon* ("possible"), which is used elsewhere.

impossible, could not come about, and if A is possible and B impossible at the same time, it would be possible for A to have come about without B; and if to have come about, then also to be, for what has come about, once it has come about, is. (We must take "impossible" and "possible" not only as they apply to coming about, but also as they apply to being true, and to belonging, and however many other ways "possible" is said: it will be alike in all of them.) Next, "if A is, B is" must not be understood to mean that if some single thing A is so, B will be so. For nothing is of necessity when a single thing is so, but instead only if at least two are, that is, when the premises are so related as was said[35] concerning deductions. For if C is predicated of D, and D of E, C will also be predicated of E of necessity; and if each is possible, the conclusion will also be possible. So, if one should put the premises as A and the conclusion as B, it follows not only that when A is necessary, B is also necessary at the same time, but also that when A is possible, B is possible.

This having been proved, it is evident that when something false but not impossible is assumed, what follows through that hypothesis will also be false but not impossible. For example, if A is false but yet not impossible, and if B is when A is, B will also be false, but not impossible. For since it has been proved that if B is when A is, B will also be *possible* when A is possible, and since A was assumed to be possible, therefore B will also be possible. For if it is impossible, the same thing will be possible and impossible at the same time.

With these matters determined, let A belong to every B and let it be possible that B belongs to every C. Then it is necessary for it to be possible that A belongs to every C. For let it not be possible, and put B as belonging to every C (this is false but not impossible). Therefore, if A is not possible to every C and B belongs to every C, A will not be possible to every B (for a deduction comes about through the third figure). But it was assumed that it is possible for A to belong to every B. Therefore, it is necessary that A is possible to every C (for when something false but not impossible is supposed, what follows is impossible). {It is also possible to produce an impossibility through the first figure, supposing as a premise that B belongs to C. For if B belongs to every C and it is possible for A to belong to every B, it would be possible for A to belong to every C: but it was assumed not to be possible for it to belong to every one.}[36]

One must suppose "belonging to every" without limiting it with respect to time (for example, "now" or "at this time") but instead unconditionally. For it is also by means of these sorts of premises that we produce deductions, since there will not be a deduction if the premise is supposed as holding only with respect to a certain moment. For perhaps nothing prevents human from belonging to everything in movement at some time (that is, if nothing else should be moving), and it is possible for moving to belong to every horse, but yet it is not possible for human to belong to

35. As in 1.1–7.

36. Rejected as spurious by most editors.

any horse. Next, let the first term be animal, the middle term moving, the last term human. The premises will be in the same relationship, then, but the conclusion will be necessary, not possible (for a human is of necessity an animal). It is evident, then, that the universal should be taken as holding unconditionally and not as determined with respect to time.

Next, let AB be a universal privative premise, and let A be assumed to belong to no B, but let it be possible that B belongs to every C. With these supposed, then, it is necessary that it is possible for A to belong to no C. For let it not be possible, and let B be supposed as belonging to C, just as previously. Then, it is necessary that A belongs to some B (for a deduction comes about through the third figure). But this is impossible; consequently, A is possible to no C: for with a false supposition what follows is impossible. This deduction, then, is not of what is possible according to our definition but rather of what belongs to none of necessity, for that is the contradictory of the hypothesis that was made (for it was supposed that A belongs to some C of necessity, and a deduction through the impossible is of the opposite affirmation). Moreover, it is also evident from terms that the conclusion will not be possible. For let A be raven, B stand for thinking, and C stand for human. Then, A belongs to no B (for nothing that thinks is a raven), while B is possible to every C (for thinking is possible for every human). However, A belongs of necessity to no C; therefore, the conclusion is not possible. Yet neither is it always necessary. For let A be moving, B scientific knowledge, C stand for human. Then A will belong to no B, while B is possible to every C, and the conclusion will not be necessary (for it is not necessary that no human be moving nor necessary that some human be). It is clear, then, that the conclusion is of belonging of necessity to none.[37] (The terms should be better chosen.)

If the privative is put with the minor extreme and signifies being possible, there will be no deduction from the premises that were actually taken, but there will be one if the possible premise is converted accordingly, as in the previous cases. For let A belong to every B and let B be possible to none of the Cs. When the terms are in this relationship, nothing will be necessary, but when BC is converted and B is supposed to be possible to every C, a deduction comes about just as before (for the terms are similarly related in position).

And in the same way with both intervals privative, if AB signifies not belonging and BC signifies being possible to belong to none. For something necessary does not result at all through the premises actually taken, but when the premise according to being possible is converted there will be a deduction. For let A have been supposed to belong to no B and B to be possible to no C. Through these premises, then, nothing is necessary, but if B is assumed to be possible to every C (which is true) and premise AB remains the same, it will again be the same deduction. But if it is supposed that B does not belong to every C, and not that it is possible for it not to belong, there

37. I.e., not of necessity to any.

will in no way be a deduction, whether premise AB is privative or positive. Terms in common for belonging of necessity are white, animal, snow; terms for not being possible are white, animal, pitch.

It is evident, then, that if the terms are universal and one of the premises is supposed as belonging, the other as possible, when it is the premise related to the minor extreme that is taken to be possible, a deduction always comes about (except that sometimes it is from the premises themselves and sometimes with a premise converted). We have said when each of these sorts of deduction comes about and through what cause.

If one of the intervals is supposed as universal and the other as particular, when the interval related to the major extreme is put as universal and possible (whether negative or affirmative), and the particular is put as affirmative and belonging, there will be a complete deduction, just as when the terms are universal. (The demonstration is the same as previously.) And when the interval related to the major extreme is universal, but belonging rather than possible, and the other interval is particular and possible, then if both premises are put as negative, or both affirmative, or one negative and the other affirmative, in all these ways there will be an incomplete deduction, although some deductions will be proved through the impossible and others through the conversion of "is possible," as in the previous cases.

There will be a deduction through conversion when the universal premise, put in relation to the major extreme, signifies belonging or not belonging[38] and the particular premise is privative and supposes being possible—for example, if A belongs or does not belong to every B and it is possible that B does not belong to some C. For a deduction comes about when BC is converted according to being possible. But when the premise put as particular supposes not belonging, there will not be a deduction. Terms for belonging are white, animal, snow; for not belonging, white, animal, pitch (the demonstration must be obtained through the indeterminate).

If the universal is put in relation to the minor extreme and the particular in relation to the major, there will in no way be a deduction, regardless of whether either term is privative or positive, possible or belonging.

Nor when the premises are put as particular or indeterminate, whether they suppose being possible, or belonging, or in alternation: there will not be a deduction in this way either. The demonstration is the same as that for the previous cases. Common terms for belonging of necessity are animal, white, human; terms for not being possible are animal, white, cloak. It is evident, then, that when the premise related to the major extreme is put as universal a deduction always comes about, but when the premise related to the minor extreme is, there is never a deduction of anything.

38. Retaining ἢ μὴ ὑπάρχειν.

1.16
First Figure: One Necessary and One Possible Premise

When one of the premises signifies belonging of necessity and the other premise signifies being possible, there will be a deduction when the terms are in the same relationship [as previously], and it will be complete whenever "necessary" is put with the minor extreme. When the terms are positive, the conclusion will be one of being possible and not belonging, whether the terms are put as universal or not universal. However, if one term is affirmative and the other privative, then when the affirmative one is necessary, the conclusion will be one of being possible rather than belonging; but if the privative term is necessary, then the conclusion may be both of being possible not to belong and of not belonging, whether the terms are universal or not universal. ("Is possible" in the conclusion must be taken in the same way as in the previous cases.) There will not be a deduction [concluding that] something of necessity does not belong, for "does not of necessity belong" is different from "of necessity does not belong."

It is evident, then, that a necessary conclusion does not come about when the terms are affirmative. For let A belong to every B of necessity, and let B be possible to every C. So, there will be an incomplete deduction that it is possible for A to belong to every C. That it is incomplete is clear from the demonstration; for it will be proved in the same way as in the previous cases. **36^a1**

Next, let A be possible to every B and let B belong to every C of necessity. There will then be a deduction that it is possible for A to belong to every C, but not that it belongs; and it will be complete rather than incomplete; for it is brought to completion directly by means of the initial premises.

If the premises are not the same in form, first let the privative premise be necessary, and let A not be possible to any B, but let B be possible to every C. Then it is necessary for A to belong to no C. For let A be supposed to belong either to every or to some C. But it was assumed not to be possible for A to belong to any B. Therefore, since the privative converts, neither is B possible to any A. But it is supposed that A belongs either to every or to some C, so that it would not be possible for B to belong to any C or (respectively) to belong to every C. But it was initially assumed [to be possible] to every. It is evident that a deduction of being possible not to belong also comes about, given that there is one of not belonging.

Next, let the affirmative premise be necessary: let it be possible that A belongs to no B, and let B belong to every C of necessity. The deduction, then, will be complete, but its conclusion will be of being possible not to belong rather than not belonging. For that is also how the premise made from the major extreme was supposed, and it cannot be reduced to the impossible (for if A should be assumed to belong to some C and also put as possible to belong to no B, nothing impossible results through these). If the privative is put with the minor extreme, when it signifies being possible there will be a deduction through conversion, as in the previous cases; but when it signifies

not being possible, there will not be one; nor, again, when both are put as privative and the premise related to the minor extreme is not possible. The terms are the same: for belonging, white, animal, snow; for not belonging, white, animal, pitch.

It will be the same way for particular deductions. For when the privative premise is necessary, the conclusion will also assert not belonging. For example, if it is not possible that A belongs to any of the Bs[39] and possible that B belongs to some one of the Cs,[40] it is necessary for A not to belong to some one of the Cs.[41] For if it belongs to every one but is not possible to any B, neither is it possible for B to belong to any A. Consequently, if A belongs to every C, B is not possible to any of the Cs:[42] but it was assumed to be possible to some. And when the particular affirmative premise in the privative deduction (that is, BC) is necessary, or the universal premise in the positive deduction is (that is, AB), there will not be a deduction of belonging. (The demonstration is the same as that in the previous cases.) If the universal premise, whether affirmative or privative, is put as possible in relation to the minor extreme and the particular as necessary in relation to the major extreme,[43] there will not be a deduction. Terms for belonging of necessity are animal, white, human; for not being possible, animal, white, cloak. When the universal is necessary and the particular is possible, then, if the universal is privative, terms for belonging are animal, white, raven, and for not belonging, animal, white, pitch; but if it is affirmative, terms for belonging are animal, white, swan, and terms for not being possible are animal, white, snow. Nor when the premises are taken as indeterminate, or both as particular, will there be a deduction in this way either. Common terms for belonging are animal, white, human; for not belonging, animal, white, inanimate (for animal both necessarily belongs to something white and is not possible to something [else] white, and [similarly] white to something inanimate; and it is the same with being possible, so that the terms are usable for all the cases).

It is evident from what has been said, then, that both in the case of belonging and in the case of necessary things, a deduction either does or does not come about with the terms in the same relationships, except that when the privative premise is put as belonging, the deduction was of being possible, whereas if the privative was supposed in the sense of necessity the deduction was both of being possible and of not belonging. {It is also clear that all these deductions are incomplete and that they are completed through the figures that were mentioned.}[44]

1.17
Second Figure: Two Possible Premises

In the second figure, when both premises suppose something being possible, there will be no deduction, whether they are put as positive or as privative, as universal or as particular. However, when one premise signifies belonging and the other signifies being possible, when it is the affirmative premise that signifies belonging, there will never be a deduction, but when it is a privative universal premise that does, there will always be one. And in the same way when one of the premises is supposed as necessary and the other as possible. (In these deductions also, one must take "possible" in the conclusions as in the previous cases.)

First, then, it must be proved that a privative premise that expresses being possible does not convert: that is, if A is possible to no B, it is not also necessary that B is possible to no A. For let this be supposed (that is, let it be possible that B belongs to no A). Then, since affirmations that express being possible convert with their negations (contraries as well as opposites), and it is possible for B to belong to no A, apparently it would also be possible for B to belong to every A. But this is false: for it is not the case that if it is possible that *this* belongs to every *that*, necessarily *that* is possible to every *this*. Consequently, the privative does not convert. Moreover, nothing prevents it being possible that A belongs to no B and yet B of necessity does not belong to some A, as, for example, it is possible for white to not belong to every human (for it may also belong), though it is not true to say that it is possible for human not to belong to anything white, for it of necessity does not belong to many of them, and what is necessary was not possible.

But neither can it be proved from the impossible that it converts, that is, if someone should claim: "Since 'It is possible for B to belong to no A' is false, 'It is not possible for B to belong to no A' is true (for they are an affirmation and its negation); and if this is true, it is true that B belongs of necessity to some one of the As.[45] Consequently, A also belongs of necessity to some one of the Bs.[46] But this is impossible." For it is not the case that if it is not possible for B to belong to no A, it is then necessary for it to belong to some. For "is not possible to no" is said in two ways: in one way if it belongs of necessity to some, and in the other way if it of necessity does not belong to some. For it is not true to say, of what of necessity does not belong to some one of the As, that it is possible for it not to belong to every one, just as it is not true either to say of what belongs of necessity to some that it is possible for it to belong to every. Therefore, if someone were to claim that since it is not possible for C to belong to every D, it of necessity does not belong to some, he would be supposing a falsehood. For [perhaps] it belongs to every one but, because it belongs to certain ones of necessity, we say, for this reason, that it is not possible for it to belong to every

45. Reading τινὶ τῶν A.
46. Reading τινὶ τῶν B.

one. Consequently, both "of necessity belongs to some" and "of necessity does not belong to some" are opposed to "possibly belongs to every" (and likewise opposite to "possibly belongs to no"). It is clear, then, that for an opposite of what is possible or not possible in the way we initially defined it, we must not only take "of necessity belongs to some" but also[47] "of necessity does not belong to some." But if this is supposed, nothing impossible results, so that no deduction comes about. It is evident from what has been said, then, that the privative premise does not convert.

With this established, let A be put as possible to no B and to every C. There will not then be a deduction through conversion (for it has been said that this sort of premise does not convert). But neither will there be one through the impossible. For if we suppose it is possible for B to belong to every C,[48] nothing false follows (for it would be possible for A to belong to every C as well as to none).

In general, if there is a deduction, clearly it would be of being possible because neither of the premises was supposed as belonging, and this deduction would be either affirmative or privative. But neither way is possible. For if we suppose the conclusion to be affirmative, it can be proved through terms that it is not possible for B to belong to C, whereas if we take it to be privative, the conclusion is not possible but instead necessary. For let A be white, B human, C stand for horse. Then it is possible for A (white) to belong to all of one and none of the other. But it is not possible for B either to belong or not to belong to C. That it is not possible for it to belong is evident, for no horse is a human. Yet neither is it possible for it not to belong: for it is necessary that no horse is a human, and the necessary was not possible. Therefore, no deduction comes about.

It can also be proved similarly if the privative is put the other way around, or if both premises are supposed as affirmative or privative (for the demonstration will be through the same terms), or when one premise is universal and the other particular, or both premises are particular or indeterminate, or in whatever other ways it is possible to alter the premises (for the demonstration will always be through the same terms). It is evident, then, that when both premises are supposed as possible, no deduction comes about.

1.18
Second Figure: One Possible and One Non-modal Premise

If one premise signifies belonging and the other signifies being possible, there will never be a deduction if the positive premise is put as belonging and the privative premise as being possible, whether the terms are supposed as universal or as particular (the demonstration is the same and through the same terms). But when

47. Reading οὐ μόνον . . . ἀλλὰ καὶ.
48. Reading τοῦ Β παντὶ τῷ Γ ἐνδέχεσθαι ὑπάρχειν.

the affirmative premise signifies being possible and the privative premise signifies belonging, there will be a deduction. For let A be supposed to belong to no B and to be possible to every C. Then, when the privative premise is converted, B will belong to no A. But A was possible to every C, so a deduction that it is possible for B to belong to no C comes about through the first figure. And similarly if the privative is put with C.

But if both premises are privative and one signifies not belonging and the other being possible, nothing necessary follows through the premises taken themselves, but when the premise in the sense of possibility is converted, a deduction that it is possible for B to belong to no C comes about, as in the previous cases (for it will again be the first figure). But if both premises are put as positive, there will not be a deduction. Terms for belonging are health, animal, human; terms for not belonging are health, horse, human.

The situation will be the same in the case of the particular deductions. For when the affirmative premise is supposed as belonging (whether taken as universal or particular), there will be no deduction (this is proved similarly to the previous cases and through the same terms); but when it is the privative premise, there will be a deduction through conversion, as in the previous cases. Next, if both intervals are supposed as privative and the one of not belonging is universal, nothing will result necessarily from the premises themselves, but when "is possible" is converted in the same way as in the previous cases, there will be a deduction. And if the privative is belonging and is supposed as particular, there will not be a deduction, no matter whether the other premise is affirmative or privative. Nor when both premises are taken as indeterminate (whether affirmative or negative) or as particular. The demonstration is the same and through the same terms.

1.19
Second Figure: One Necessary and One Possible Premise

If one of the premises signifies belonging of necessity and the other premise signifies being possible, when it is the privative premise that is necessary there will be a deduction, not only that it is possible for something not to belong, but also that it does not belong; but when it is the affirmative premise, there will not be a deduction.

For let A be supposed to belong of necessity to no B and to be possible to every C. Then when the privative premise is converted, neither will B belong to any A. But A was possible to every C, so a deduction that it is possible for B to belong to no C comes about again through the first figure. At the same time, it is clear that B will also not belong to any of the Cs.[49] For suppose it does belong. Then, if A is possible to no B and B belongs to some one of the Cs, A will not be possible to some one of

49. Reading τῶν Γ.

the Cs.[50] But it was assumed that it is possible for it to belong to them all. It can be proved in the same way if the privative is put with C.

Next, let the positive premise be necessary and the other premise possible, and let A be possible to no B, but let A belong of necessity to every C. When the terms are related like this, there will be no deduction, for it may happen that B of necessity does not belong to C. For let A be white, B stand for human, C stand for swan. Then white belongs to swan of necessity and is possible to no human, and human belongs to no swan of necessity. It is evident, then, that there is no deduction of being possible, for what is of necessity was[51] not possible. But neither is there a deduction of a necessary conclusion; for a necessary one followed either from both premises being necessary or from the privative premise being so. Moreover, it is possible when these things are supposed for B to belong to C. For nothing prevents C being below B and A being possible to every B and belonging of necessity to C, as, for example, if C is awake, B is animal, and A stands for movement: for movement belongs of necessity to what is awake and is possible to every animal, and everything awake is an animal. It is evident, then, that neither is there a deduction of not belonging, given that when the terms are like this it is necessary for B to belong to C. But neither is there a deduction of the opposite affirmations. Consequently, there will be no deduction. It can be proved similarly if the affirmative premise is put the other way around.

If the premises are the same in form, when they are privative there will always be a deduction when the premise expressing possibility is converted, as in the previous cases. For let A be supposed not to belong to B of necessity and possibly not to belong to C. Then, when the premises arc converted, B belongs to no A and A is possible to every C, so it becomes the first figure. Likewise, if the privative is put in relation to C. However, if positive premises are supposed, there will not be a deduction. For it is evident that there will not be one of not belonging or of not belonging of necessity, because a privative premise was not supposed, either as expressing belonging or as expressing belonging of necessity. But neither will there be a deduction of possibly not belonging. For with the terms in this relationship, B may of necessity not belong to C (for example, if A is put as white, B stands for swan, C is human). Yet neither will there be a deduction of the opposite affirmations, since B has been proved as of necessity not belonging to C. Therefore, no deduction comes about at all.

It will be likewise in the case of the particular deductions. For whenever the negative premise is both universal and necessary, there will always be a deduction both of being possible and of not belonging (the demonstration is through conversion); but when it is the affirmative premise, there never will be one. For this can be proved in the same way as in the case of the universal deductions and through the same terms. Nor when both premises are taken as affirmatives (for the demonstration of this is also the same one as before). But when both premises are privative and the one

50. Reading τινὶ τῶν Γ twice.
51. 32a18–20, 32a36.

signifying not belonging is both universal and necessary, a necessary result will not come about by means of the premises taken themselves, but there will be a deduction when the premise expressing being possible is converted, as in the previous cases. And if both premises are put as indeterminate or as particular, there will not be a deduction (the demonstration is the same and through the same terms).

It is evident from what has been said, then, that when the privative universal premise is supposed as necessary, a deduction always comes about not only of being possible not to belong but also of not belonging, but that a deduction never comes about when the affirmative premise is put as necessary. It is also evident that deductions both do and do not result with the terms in the same relationships in the case of necessary premises as in the case of premises of belonging. It is also clear that all these deductions are incomplete and that they are completed through the figures that were mentioned.

1.20
Third Figure: Two Possible Premises

In the last figure, there will be a deduction when both premises are possible and also when only one of them is. When the premises signify being possible, then, the conclusion will also be possible, and also when one premise signifies being possible and the other signifies belonging. However, when one premise is supposed as necessary, if it is affirmative the conclusion will not be either necessary or belonging, but if it is privative there will be a deduction of not belonging as in the previous cases. In these deductions as well, we must understand "possible" in the conclusions in the same way.

Let the premises first be possible, then, and let it be possible that both A and B belong to every C. Then, since the affirmative premise converts in part and B is possible to every C, C will also be possible to some B. Consequently, if A is possible to every one of the Cs[52] and C to some B, it is also necessary for A to be possible to some one of the Bs[53] (for it becomes the first figure). And if it is possible that A belongs to no C and B belongs to every C, it is necessary for it to be possible that A does not belong to some B (for it will be the first figure again through conversion). If both premises are put as privative, there will be no necessary result from the premises taken themselves, but there will be a deduction when the premises have been converted, as in the previous cases. For if it is possible that both A and B do not belong to C, if "is possible to belong" is substituted, it will again be the first figure through conversion.

And if one of the terms is universal and the other is particular, there will either be, or fail to be, a deduction when the terms are in the same relationship as in the case

52. Reading παντὶ τῶν Γ.
53. Reading τινὶ τῶν Β.

of belonging. For let A be possible to every C and B to some C. Then it will be the first figure again if the particular premise is converted. For if A is possible to every C and C to some one of the Bs, A is possible to some B. And if the universal is put with BC, likewise. And similarly if AC should be privative and BC affirmative (for it will again be the first figure through conversion). But if both premises are put as privative, one as universal and the other as particular, there will not be a deduction through the premises taken themselves, but when they are converted there will be, as in the previous cases. But when both premises are taken as indeterminate or as particular, there will not be a deduction. For A can be necessary both to every and also to no B: terms for belonging are animal, human, white; for not belonging, horse, human, white (white is the middle term).

1.21
Third Figure: One Possible and One Non-modal Premise

If one of the premises signifies belonging and the other signifies being possible, the conclusion will be that it is possible, not that it belongs, and there will be a deduction when the terms are in the same relationships as in the previous cases. First let the terms be positive, and let A belong to every C, but let it be possible that B belongs to every C. Then, when BC is converted, it will be the first figure, and the conclusion will be that it is possible that A belongs to some one of the Bs.[54] For when one or the other of the premises in the first figure signifies being possible, the conclusion was[55] also possible. Similarly, if BC signifies belonging and AC signifies being possible, or if AC is privative and BC positive (and either one is belonging), in both ways the conclusion will be possible. For it becomes the first figure again, and it was proved that in it, if one or the other premise signifies being possible, the conclusion will also be possible. But if the privative is put in relation to the minor extreme, or again if both premises should be taken as privative, there will not be a deduction through the assumptions themselves, but there will be one when they have been converted, as in the previous cases.

If one of the premises is universal and the other is particular, when both premises are positive, or when the universal premise is privative and the particular premise is affirmative, there will be deductions in the same way. For they all come to a conclusion through the first figure; consequently, it is evident that the deduction will be of being possible and not of belonging. But if the affirmative premise is universal and the privative premise is particular, the demonstration will be through the impossible. For let B belong to every C, and let it be possible that A does not belong to some C. Thus, it is necessary for A to be possible not to belong to some B. For if A belongs of

54. Reading τινὶ τῶν B.
55. 1.15.

necessity to every B and B is put as belonging to every C, A will belong to every C of necessity (for this was proved earlier): but it was assumed to be possible for A not to belong to some C.

When both premises are taken as indeterminate or as particular, there will not be a deduction. The demonstration is the same as in the previous cases and through the same terms. **40^a1**

1.22
Third Figure: One Necessary and One Possible Premise

If one of the premises is necessary and the other is possible, when the terms are positive there will always be a deduction of being possible. But when one is positive and the other privative, if the affirmative is necessary, the deduction will be of being possible not to belong, while if the privative is necessary, it will be both of being possible to belong and of not belonging. But there will not be a deduction of not belonging of necessity, just as there was not one in the other figures.

First, then, let the terms be positive, and let A belong to every C of necessity, but let B be possible to every C. Then, since it is necessary that A belongs to every C and C is possible to some B, "A to some B" will also be possible (not belonging): for that is the way it happened in the case of the first figure. If BC is put as necessary and AC as possible, it will be proved similarly. Next, let one term be positive, the other privative, and the positive necessary, that is, let it be possible that A belongs to no C, and let B belong to every C of necessity. It will then be the first figure again. For since the privative premise signifies being possible, it is therefore evident that the conclusion will be possible: for when the premises are like this in the first figure, the conclusion was also possible. But if the privative premise is necessary, the conclusion will be both that it is possible not to belong to some and that it does not belong. For let A be put as not belonging to C of necessity, and let B be possible to every C. Then, when the affirmative BC is converted, it will be the first figure, and the privative premise will be necessary. And when the premises are like this, it turned out[56] both that it is possible for A not to belong to some C and that it does not belong, so that it is also necessary that A does not belong to some B. But when the privative is put in relation to the minor extreme, then, if it is possible, there will be a deduction when the premise is substituted as in the previous cases. But if it is necessary, there will not be a deduction; for it [may] both belong necessarily to all and also be possible to belong to none. Terms for belonging to all are sleep, sleeping horse, human; for belonging to none, sleep, waking horse, human.

It will be similar if one of the terms is universal and the other particular in relation to the middle. For when both are affirmative, there will be a deduction of

56. 36^a17–25.

40ᵇ1 being possible but not of belonging, and also when one is taken as privative and the other as affirmative and the affirmative is necessary. But when the privative is necessary, the conclusion will also be one of not belonging. For the way of proving them will be the same whether the terms are universal or not universal. For it is necessary to complete the deductions through the first figure, and so it necessarily happens the same way in these cases as it did in those. But when the privative premise is taken as universal in relation to the minor extreme, if this premise is possible there will be a deduction through conversion, but if it is necessary there will not be. This will be proved in the same way as in the universal cases and through the same terms.

It is evident, then, both when and how there will be a deduction in this figure, and when it will be of being possible and when of belonging. It is clear too that the deductions are all incomplete and that they are completed through the first figure.

1.23
All Deductions Whatever Can Be Reduced to the First Figure

It is clear from what has been said, then, that the deductions in these figures are both completed through the universal deductions in the first figure and reduced to them. But it will now be evident that this holds for all deductions unconditionally when it has been proved that all of them come about through one of these figures.

Every demonstration and every deduction must prove something either to belong or not to belong, and this either universally or particularly, and in addition either probatively or from a hypothesis (for deduction through the impossible is a part of deduction from an assumption). First, then, let us discuss probative cases, for when these have been proved, the result will also be evident both for those that reduce to the impossible and generally for those from a hypothesis.

If someone must deduce A of B, either as belonging or as not belonging, it is necessary to suppose something of something. If A is taken of B, then that will be supposing the initial thing. But if A is supposed of C, and C of nothing nor anything else of it, nor some other thing of A, there will be no deduction, for nothing results of necessity in virtue of one single thing having been supposed of another. Consequently, another premise must be supposed in addition. If A is then supposed of something else, or something else of it or of C, nothing prevents there being a deduction, but it will not be in relation to B through the premises taken. Nor when C is supposed to belong to something else, that to another thing, and this to something else, but it does not connect to B: there will not be a deduction
41ᵃ1 in relation to B in this way either. For we said that in general, it is never possible to deduce one thing of another without some middle term having been supposed

which is related in some way to each according to the sorts of predications.[57] For a deduction, unconditionally, is from premises; a deduction in relation to this term is from premises in relation to this term; and a deduction of this term in relation to that is through premises of this term in relation to that. And it is impossible to take a premise in relation to B without either predicating or denying anything of it, or again to get a deduction of A in relation to B without taking any common term, but just predicating or denying certain things separately of each of them. As a result, something must be taken as a middle term for both that will connect the predications, if there is actually to be a deduction of this term in relation to that. Therefore, if it is necessary to suppose some common term in relation to both, and if this is possible in three ways—that is, by predicating A of C and C of B, or C of both A and B, or both A and B of C—and these ways are the figures we said, it is evident that every deduction must come about through some one of these figures. (The argument will be the same if A connects with B through more things: for the figure will be the same even in the case of many terms.)

It is evident, then, that probative deductions are brought to a conclusion through the figures stated previously. But that this holds for deductions reducing to the impossible as well will be clear through these next considerations. For all those that come to a conclusion through the impossible *deduce* the falsehood but *prove* the initial thing from a hypothesis, when something impossible results from assuming its contradictory—for example, proving that the diagonal is incommensurable because if it is assumed to be commensurable, odd numbers become equal to even ones. It *deduces* that odd numbers become equal to even ones, then, but it *proves* that the diagonal is incommensurable from a hypothesis, since a falsehood follows because of its contradictory. For this is what was meant[58] by "deducing through the impossible": proving something impossible through the initial hypothesis. Consequently, since a probative deduction of the falsehood comes about in those cases that reduce to the impossible (while the initial thing is proved from a hypothesis), and we said earlier that probative deductions are brought to a conclusion through these figures, it is evident that deductions through the impossible will also be through these figures. And likewise for all the other sorts of deduction from an assumption. For in all of them, the deduction is in relation to the substituted proposition, and the initial thing is concluded through an agreement or some other sort of hypothesis. But if this is true, every demonstration and every deduction must necessarily come about through the three figures mentioned previously. With this proved, it is clear that every deduction is both brought to completion through the first figure and reduced to the universal deductions in it.

57. I.e., to every, no, some, or not to some.

58. Not defined previously in *APr.*, but see 2.11.

1.24
Some General Results about Deductions

Moreover, in every deduction one of the terms must be positive and there must be a universal. For without a universal, either there will not be a deduction, or it will not be in relation to what was proposed, or it will be asking for the initial thing.[59] For let it be proposed [to prove] that musical pleasure is excellent. Then, if someone should claim "pleasure is excellent," without adding "every," there will not be a deduction. But if he should claim "some pleasure is excellent," then if it is another pleasure, that is nothing in relation to what was proposed, whereas if it is this very pleasure, he is taking the initial thing.

This becomes more evident in geometrical proofs—for example, the proof that the angles at the base of an isosceles triangle are equal. Let the lines AB be drawn toward the center. Then, if someone should suppose angle AC to be equal to angle BD without claiming that in general the angles of semicircles are equal, or next that C is equal to D without supposing this in addition for every angle of a segment, or in addition supposes "if equal angles are taken away from the whole angles, which are equal, the remainders E and F are equal," without taking equal things to remain when equals are subtracted from equals, he will be asking for the initial thing.

It is evident, then, that every deduction must include belonging universally, and also that the universal is proved from all the terms being universal, while the particular is proved both in this way and in the other way. As a result, if the conclusion is universal the terms must also be universal, while if the terms are universal it is possible for the conclusion not to be universal. It is also clear that in every deduction either both premises or one of them must be like the conclusion (I mean not only with respect to being affirmative or privative, but also with respect to being necessary or belonging or being possible). The other sorts of predications must also be examined.

It is evident, then, both when there will unconditionally be or not be a deduction, and when it will be potential and when perfect, and also that if there is a deduction it is necessary for the terms to be related in accord with one of the ways we said.

1.25
Further Results about Extended Deductions

It is also clear that every demonstration will be through three terms, and no more, unless the same conclusion comes about through different pairs of premises—for example, E through A and B and also through C and D, or through A and B and also through A, C, and D (for nothing prevents there being several middles for the same terms; but when there are, there is not one deduction but several), or again when

59. Explained in 2.15.

each one of A and B is obtained through a deduction—for example, A through DE and next B through FG, or one through induction and the other through deduction. (But in this way also the deductions are more than one, for the conclusions are more than one—that is, A, B, and C.) If, therefore, this is not many deductions but one, then it is possible in this way for the same conclusion to come about through more [than three] terms. However, it is impossible for this to happen in the way that C results through A and B. For suppose that E has been concluded from ABCD, then some one of them must necessarily have been supposed in relation to another term, one as whole and the other as part (for this was proved earlier,[60] that is, that if there is a deduction, it is necessary for some of the terms to be related in this way). Then let A be so related to B. Therefore, there is some conclusion from them. It will be either E, or one of CD, or something else besides these. But if it is E, the deduction would be from A and B alone. And if C and D are so related as to be one a whole and the other a part, there will also be some conclusion from them, and it will be either E or one of A and B or something else besides these. If it is E or one of A and B, either there will be several deductions, or it will follow in the way it was possible for the same thing to be concluded through multiple terms. But if it is something else besides these, the deductions will be multiple and not connected to each other. And if C is not so related to D as to make a deduction, these premises will have been taken to no purpose (unless for the sake of induction, or concealment, or something else of that sort). **42a1**

If instead of E some other conclusion comes about from A and B, and if the conclusion from C and D is either one or the other of these or something else besides them, the deductions become both many and not of the underlying subject (for the deduction was assumed to be of [conclusion] E). And if no conclusion comes about from C and D, it results both that they were assumed to no purpose and that the deduction is not of the initial thing. So it is evident that every demonstration and every deduction will be through only three terms.

And since this is evident, it is clear that it will also be from two premises and no more (for three terms are two premises), unless something should be supposed in addition for the purpose of completing the deductions, as was said in our initial remarks.[61] It is evident, then, that if the premises in a deductive argument through which the principal conclusion results are not even in number (for some of the upper conclusions are necessarily premises) then that argument either has not deduced or has asked for more things than are necessary in relation to the proposition.

Counting deductions by their principal premises, then, every deduction will be from an even number of premises and an odd number of terms (for the terms are one more in number than the premises). Also, the conclusions will be half as many as the premises. And when the conclusion is reached through prior deductions or through **42b1**

60. 1.23.
61. $24^{b}22–26$.

several continuous middle terms (for example, if premise AB is concluded through terms CD), the number of terms will likewise exceed the premises by one (for the term inserted will be put either outside or in the middle [of the interval], but in both ways it results that the intervals are one fewer than the terms, and the premises are equal in number to the intervals). However, the premises will not always be even and the terms odd, but in alternation: when the premises are even, the terms will be odd, and when the terms are even, the premises will be odd. For a single premise is added at the same time as a term, no matter from what side the term may be added, so that since the premises were even and the terms odd, this will necessarily alternate when the same addition has been made. But the conclusions will no longer be ordered in the same way either with respect to the terms or with respect to the premises. For when one term is added, conclusions will be added one fewer in number than the terms which were already present: for only in relation to the last term does it fail to produce a conclusion, while it produces one in relation to all the rest. For example, if D is added to ABC, two conclusions are added immediately, one in relation to A and one in relation to B (and similarly in the other cases). It will also be the same way if the term is inserted in the middle (for it will only fail to produce a deduction in relation to one of them). Consequently, the conclusions will be much greater in number than either the terms or the premises.

1.26
Which Problems Are Easiest to Prove and Which Hardest

Since we now know what deductions are about, and what sort of problem is proved in each figure and in how many ways, it is also evident to us what sort of problem is difficult and what sort easy to attack. For what is concluded in more figures and through more inflections[62] is easier to attack, and what is concluded in fewer figures and by means of fewer cases more difficult. The affirmative universal, then, is proved through the first figure alone, and through it in only one way. The privative universal is proved both through the first figure and through the middle (through the first in one way, through the middle in two). The particular affirmative is proved through the first and through the last (in one way through the first and in three ways through the last). The privative particular is proved in all the figures: in the first figure it is proved in one way, while in the middle and in the last figures it is proved in two ways and in three, respectively.

43a1 It is evident, then, that the universal positive is most difficult to establish but easiest to disestablish. And in general, a universal is easier to do away with than a particular. For if it either belongs to none or does not belong to some, it has been

62. Here and at 43a10, 42b30, 49a2, and 94a12 an "inflection" (*ptôsis*) is a particular form (or "mood") of deduction.

done away with; and of these, not belonging to some is proved in all the figures, while belonging to none is proved in two of them. And it is the same way for the privatives; for if it belongs either to every or to some, the initial problem has been done away with, and this was proved in two figures. But in the case of the particulars, the problem is done away with only in one way, that is, by proving to belong either to all or to none.

But in establishing, the particular problems are easier, for they are proved in more figures and through more inflections.[63] And in general, it must not be overlooked that it is possible to do away with the problems through each other, that is, both universals through particulars and particulars through universals, but that it is not possible to establish universals through particulars, although it is possible to establish the latter through the former (but at the same time it is clear that it is easier to disestablish than to establish).

From what has been said, then, it is clear how every deduction comes about, both through how many terms and premises and how they are related to each other, and furthermore what sort of problem is proved in each figure, and what sort in more and what in fewer figures.

1.27
How to Find Deductions: Selecting Premises

Now it is time to explain how we may ourselves always be well supplied with deductions about whatever is proposed, and the route by which we can obtain the starting-points concerning any subject. For surely we should not only observe how deductions come about, but also to have the capacity to produce them.

Among all the things that are, some are such as not to be predicated truly and universally of anything else (for example, Cleon and Callias and what is particular and perceptible) but to have other things predicated of them (for each of these is both a human and an animal); some are themselves predicated of others but do not have other prior things predicated of them; and some are both predicated of others and have others predicated of them (for example, human is predicated of Callias and animal of a human).

So then, among all the beings, some are not of such a nature as to be said of anything is clear; for each perceptible object is pretty much the sort of thing that cannot be predicated of anything except coincidentally (for we do sometimes say that this white thing is Socrates, or that what is approaching is Callias). And that it also comes to a stop at some point proceeding in the upward direction we will explain later:[64] for the present, let this be supposed. Of these things, then, it is not possible to

63. Reading πτώσεων.
64. 1.15, 1.22.

demonstrate that anything else is predicated (except in accord with belief), but they are predicated of others. Neither can particulars be predicated of other things, but instead other things are predicated of them. But it is clear that for those in between, predication is possible in both ways (for they can be said of other things, and other things can also be said of them). And arguments and inquiries are probably always concerned mostly with these things.

43b1 So, we must select the premises about any subject in this way: first, assume the subject itself (its definitions, and also what is special to it); next, after this, whatever follows the subject; next, whatever the subject follows; and then, whatever cannot belong to it. (Those to which it is not possible for the subject to belong need not be selected, because the privative converts.) The terms that follow the subject must also be divided into those predicated of it in the what-it-is, those special to it, and those predicated coincidentally, and of these, also, which are in accord with belief and which are in accord with the truth. For the more such terms one is supplied with, the more quickly hit on a conclusion, while to the extent that one is supplied with more that is true, the more will one demonstrate.

We must select those things that follow the subject as a whole, not those that follow some of it (for example, not what follows some human, but what follows every human); for a deduction is through universal premises. So then, when a premise is indeterminate, it is unclear whether it is universal, whereas if it is determinate this is evident. Similarly, we must select what the subject follows as a whole for the reason stated. However, we must not take what follows to follow as a whole (I mean, for example, taking every animal to follow human or every science to follow music), but only to follow unconditionally, in the same way that we also propose premises. For the other way—for example, that every human is every animal or justice is every good, is both useless and impossible. Instead, it is what the subject follows that "every" should be put with.

When the subject for which one needs to select the things that follow is contained under something, those following or not following that [containing] universal need not be selected for inclusion in these (for they were already included in the former terms: for whatever follows animal also follows human, and likewise for those which do not belong). But those that are special concerning each subject should be taken. For there are certain things special to a form besides its kind, since it is necessary for some special affections to belong to each of the various forms. Nor, again, should what the contained term follows be selected for the [containing] universal—for example, taking what human follows in the selection for animal (for if animal follows human, it is necessary for it to follow all of these, but they are more appropriate to the selection for human). Those things that follow or are followed for the most part should also be taken. For deductions of problems that are for the most part are also from premises that are for the most part (either all or some of them); for the conclusion of each deduction is like its starting-points. In addition, those that follow

everything should not be selected, for there will not be a deduction from them (the cause of this will be clear in what follows).

1.28
Finding Premises from Which to Deduce a Given Conclusion

If we want to establish something of some whole, we should look at the subject terms that the predicate to be established is said of and those that follow the term that this term is to be predicated of. For if there is something the same in these groups, the one term must belong to the other. If we need to establish, not that it belongs to every, but that it belongs to some, we must look at those that each term follows. For if something in these groups is the same, it is necessary that it belongs to some. When we need [to prove] belonging to none, then regarding the term that the predicate must be proved not to belong to, we must look at the things that follow it and, regarding the term that needs not to belong to it, we must look at the things that cannot be present in it; or, the other way around, regarding the term that the predicate must be proved not to belong to, we must look at the things that cannot be present in it, and, regarding the term that needs not to belong, we must look at the things that follow it. For if either of these is the same, it will not be possible that the one term belongs to any of the other. (Sometimes a deduction in the first figure comes about, sometimes one in the middle figure.) And to prove not belonging to some, regarding the term that the predicate must be proved not to belong to, we must look at the things that follow it, and regarding the term that needs to not belong, we must look at the things that cannot be present in it. For if some one of these is the same, it is necessary that [the predicate] proposed does not belong to some [of the subject].

Perhaps each of these statements will be clearer in the following way. Let B stand for those that follow A, let C stand for those that A follows, and let D stand for those that cannot belong to A. Next, let F stand for those that belong to E, G stand for those it follows, and H for those that cannot belong to it. Accordingly, if one of the Cs should be the same as one of the Fs, it is necessary for A to belong to every E (for F belongs to every E and A to every C, so that A belongs to every E). But if a C and a G are the same, it is necessary for A to belong to some one of the Es[65] (for A follows every C and E follows every G). And if an F and a D are the same, A will belong to none of the Es, from a preparatory deduction (for since the negative converts and the F is the same as the D, A will not belong to any of the Fs, but F belongs to every E). Next, if a B and an H are the same, A will belong to none of the Es (for the B will belong to every A but to none of what E stands for: for the B was the same as the H, and the H belonged to none of the Es). And if a D and a G are the same, A will not belong to some one of the Es (for it will not belong to the G, because it does not

65. Reading τινὶ τῶν E.

belong to the D either; but the G is below E, so that it will not belong to some one of the Es[66]). But if a B is the same as a G, there will be a converted deduction. For E will belong to every A (for the B will belong to A, and E to the B, since it was the same as the G); and though it is not necessary that A belongs to every E, it is necessary for it to belong to some, because the universal predication converts into a particular. It is evident, then, that with respect to each problem one must look at what was previously said for each of its terms (for all the deductions are through these).

In addition, among both those things which follow each term and those which are followed by it, one must look at those that are primary and most universal. For example, when it comes to E, one must look at KF rather than F alone. Or, when it comes to A, one must look at KC rather than C alone. For if A belongs to KF, it also belongs to F and to E, whereas if it does not follow the latter, it still is possible for it to follow F. Those that the subject itself follows must be examined in the same way. For if something follows the first terms, it follows those below them, although if it does not follow the latter, it is still possible for it to follow those below the former.

It is also clear that the inquiry is through the three terms and the two premises, and that all the deductions are through the figures said previously. For A is proved to belong to every E when we get some same term from among the Cs and the Fs. But this will be the middle term, and A and E the extremes; therefore, it becomes the first figure. A is proved to belong to some E when we get a C and a G that are the same. But this is the last figure; for the G becomes the middle term. A [is proved to belong] to no E when we get a D and an F that are the same. But in this way, both the first figure and the middle come about: the first because A belongs to no F (since the privative converts) and F belongs to every E, and the middle because the D belongs to no A and to every E. And [A is proved] not to belong to some E when a D and G are the same. But this is the last figure; for A will belong to no G and E to every G. It is evident, then, that all the deductions are through the figures we said previously, and also that we need not select terms that follow everything because no deduction comes about from them. For it was overall not possible to establish just from what follows something, and it is not possible to refute by means of what follows everything (for it must belong to one and not belong to the other).

It is also evident that the other inquiries that are in accord with these selections are useless for producing a deduction—that is, whether terms following each are the same, or whether terms A follows are the same as those that are not possible to belong to E, or next whether terms that cannot belong to each term are the same. For no deduction comes about through these. For if terms that follow each term are the same—that is, a B and an F—it will become the middle figure with the premises positive; if terms that A follows are the same as terms that are not possible to E—that is, a C and an H—it will be the first figure with the premise related to the minor extreme privative; and if terms that cannot possibly belong to each are the same—that is, a D

66. Reading τινὶ τῶν E.

and an H—both premises will be privative, either in the first or in the middle figure. But in none of these ways is there a deduction.

It is also clear that we must take terms that are the same, not terms that are different or contrary, as the terms selected for the investigation. This is so in the first place because the examination is for the sake of a middle term, and we must take as middle something the same, not something different. Moreover, those cases in which a deduction does result, through taking contraries or terms that cannot belong to the same thing, can all be reduced to the ways previously said. For example, suppose a B and an F are contraries or that it is not possible for them to belong to the same thing. If we get these, there will be a deduction that A belongs to none of the Es. However, it will not be from these terms themselves, but rather from the way said previously. That is, B will belong to every A and to no E, so that B must be the same as some one of the Hs.[67]

{Next, if it is not possible for a B and a G to be present in the same thing, [there will be a deduction] that A will not belong to some one of the Es.[68] For in this way also it will be the middle figure. For B will belong to every A, but to no E, so that it is necessary for the B to be the same as some one of the Hs: for there is no difference between it not being possible for a B and a G to belong to the same thing and the B being the same as some one of the Hs, since everything that cannot belong to E was taken.}[69]

It is evident, then, that no deduction comes from these inspections themselves. However, if a B and an F are contraries, the B must be the same as some one of the Hs, and the deduction must come about through these terms. The result, then, is that those who examine in this way are carrying out a superfluous examination through a different route from the one needed, because they overlook the identity of the Bs and the Hs.

1.29
Deduction by Deduction to the Impossible

The circumstances concerning deductions by reducing to the impossible are the same as for probative ones. For they too come about through what each term follows or is followed by, and the same inquiry applies in both. For whatever is proved probatively can also be deduced through the impossible through the same terms, and whatever is proved through an impossibility can also be deduced probatively—for example, that A belongs to none of the Es.[70] For suppose it belongs to some. Then, since B belongs

67. Reading τινὶ τῶν Θ.
68. Reading τινὶ τῶν Ε.
69. Secluded as a confused later addition.
70. Reading οὐδενὶ τῶν Ε.

to every A and A to some one of the Es,[71] B will belong to some one of the Es: but it belonged to none. Next, [a proof] that it belongs to some. For if A belongs to none of the Es and E to all of the Gs,[72] A will belong to none of the Gs: but it belonged to them all. Similarly, also for the other problems: for always and in every case, the proof through the impossible will be from what each of the terms follows or is followed by.

And the inquiry is the same, with respect to each problem, whether we intend to deduce probatively or reduce to the impossible. For both demonstrations are made from the same terms. For example, if A has been proved to belong to no E because it follows that B also belongs to some one of the Es,[73] and this is precisely what is impossible: if B is taken to belong to no E and to every A, it is evident that A will belong to no E. Next, if it has been deduced probatively that A belongs to no E, by assuming that it belongs to some, it will be proved to belong to none through the impossible. And it is similar in the other cases. For in them all, it is necessary to take some common term different from those assumed which the deduction of the falsehood will be in relation to; consequently, if this premise is converted while the other premise remains the same, the deduction will be probative through the same terms. For the probative deduction differs from the one to the impossible because in the probative deduction both the premises are supposed in accord with the truth, whereas in the deduction to the impossible one premise is supposed falsely.

These things will be more evident in the course of the following remarks, when we come to discuss proof through the impossible, but for now let this much be clear to us: that one must look at the same things whether one wants to deduce probatively or to lead to the impossible. In other deductions from a hypothesis, for example, those according to substitution or according to quality, the inquiry will be conducted concerning the terms assumed—not the initial ones, but those substituted—and the manner of the examination will be the same. (We need to examine this further and divide up the different ways of deducing from a hypothesis.)

Each of the problems is proved in this way, then, but there is also another way to deduce some of them—for example, deducing universals from a hypothesis through the examination of a particular. For if a C and a G were the same and E should be supposed to belong only to Gs, A would belong to every E. Again, if a D and a G are the same and E should be predicated only of Gs, it follows that A will belong to none of the Es.[74] It is evident, then, that we should also look over the terms in this way.

And it is the same way in the case of the necessary and the possible, for the way of inquiry is the same, and the deduction of being possible will be through terms arranged in the same way as for the deduction of belonging. But in the case of possible propositions, we must also select the terms that do not belong but are capable[75]

71. Reading τινὶ τῶν E.
72. Reading μηδενὶ τῶν E . . . παντὶ τῶν H.
73. Reading τινὶ τῶν E.
74. Reading οὐδενὶ τῶν E.
75. *Dunaton* (as at 34a5–33).

of belonging (for it was proved that a deduction of being possible also comes about through these). Similarly for the other sorts of predication.

It is evident from what has been said, then, not only that it is possible for all deductions to come about through this route, but also that this is impossible through any other. For every deduction has been proved to come about through one of the figures previously mentioned, and these cannot be constructed except through what each term follows or is followed by: the premises and the selection of a middle are from these, so that it is not even possible for a deduction to come about through others.

1.30
This Method Is the Universal Method for Any Subject

The route is the same with respect to all things, then, whether concerning philosophy or concerning any sort of craft or learning whatever. For we must discern what belongs to each term and what it belongs to, and be supplied with as many of them as possible, and examine these through the three terms, disestablishing in this way and establishing in that; according to truth, from terms that have been cataloged as belonging in accord with truth, but in dialectical deductions from premises that are in accord with belief.

The starting-points of deductions have been described universally—both what they are like and how we should hunt for them—in order that we might not look to everything that is said of something or inspect the same things when establishing as when disestablishing, or the same things when establishing something to belong to all as to some, or when disestablishing a predicate of all as of some, but rather that we should look to fewer and determinate things, and that we should make a selection concerning each thing that is (for example, concerning the good or science).

The majority of the starting-points of each science are special to it. That is why it is the role of our experience to deliver to us the starting-points concerning any given subject. I mean, for example, that it is astronomical experience that delivers the starting-points of astronomical science (for when the appearances had been sufficiently grasped in this way, astronomical demonstrations were found), and similarly concerning any other craft or science whatever. Consequently, once the facts concerning any subject have been grasped, it is then already within our grasp to bring the demonstrations readily to light. For if nothing that truly belongs to the things has been left out of our recorded cases, then concerning every case, if a demonstration for it exists, we will be able to find that demonstration and demonstrate it, while if it does not naturally have a demonstration, we will be able to make that evident.

The way we should select premises has been sufficiently explained in general, then. We have gone through this in exact detail, however, in our study concerning dialectic.[76]

1.31
Comparison with the Method of Division

It is easy to see that division through kinds is only a small part of the methodical inquiry that has been described. For division is a sort of weak deduction: it asks for what needs to be proved and always deduces one of the things higher up. But to begin with, this very point had been overlooked by all those who made use of it, and they used to try to persuade us that it is possible for there to be a demonstration concerning substance and the what-it-is. Consequently, they understood neither what it is possible to deduce by dividing nor that it was possible to deduce in the way we have said. In demonstrations, when we must deduce something to belong, the middle term through which the deduction comes about must always be both less than the first of the extremes and not universal of it. Division, however, means just the opposite: it takes the universal as a middle term. For example, let A stand for animal, B stand for mortal, and C stand for immortal, and let D stand for human, the definition of which we must get. Division then supposes that every animal is either mortal or immortal, which is to take everything that is A to be either B or C. Next, as the division continues, it takes a human to be an animal, so that it takes A to belong to D. The deduction, then, is that every D will be either B or C, so that it is necessary that a human is either mortal or immortal. To be a mortal animal, however, is not necessary but instead is taken as a posit: yet this is what it was required to deduce. Next, putting A to be mortal animal, B to stand for footed, C to stand for footless, and D human, the person dividing likewise supposes that A is either in B or in C (for every mortal animal is either footed or footless), and that A is predicated of D (that is, it supposes human to be a mortal animal), so that it is necessary that a human is either a footed or a footless animal. But to be footed is not necessary, and instead he supposes this: but that was again what it was required to prove. So it results that those who keep dividing in this way always take the universal—that is, the subject about which it was required to prove—as their middle term and take its differences as their extremes. But as for the final result—that this is what human is, or whatever it might be that is being sought—they do not say anything at all clear about why this is necessary. For indeed, they follow out their different route in its entirety without even thinking that the possible ways to proceed exist.

It is also evident that one can neither disestablish through this procedure nor deduce something concerning a coincident or a special affection, or about a kind,

76. The reference is probably to *Top*. 1.14.

or deduce in those cases in which it is not known whether the facts are this way or that, such as whether the diagonal of a square is incommensurable or commensurable [with its side]. For if someone supposes that every length is either commensurable or incommensurable and that the diagonal is a length, he has deduced that the diagonal is either commensurable or incommensurable. However, if he supposes it to be incommensurable, what needed to be deduced will be taken. Therefore, it cannot be proved: for this is his route, and through this route it cannot be done. Let A stand for "incommensurable or commensurable," B length, C diagonal. It is evident, then, that this way of investigation is neither suitable for every inquiry, nor even useful in those very cases in which it appears to be most fitting. It is therefore evident from what has been said what all demonstrations come from, and how they do so, and what things we should look at in the case of each problem.

1.32
Reducing All Deductions to the Deductions in the Figures

But after these matters, we must say how we can reduce deductions to the figures previously mentioned, for this is still missing from our inquiry. For if we should both **47^a1** have a theoretical understanding of how deductions come into being and also have the power of finding them, and if moreover we can analyze deductions that have already been produced into the figures previously mentioned, our initial project will have attained its end. It will follow at the same time that what we have said previously will be made more secure, and that this is how matters stand will be made clearer by what we are now about to say: for all that is true must be in agreement with itself in every way.

First, then, we must try to select the two premises of the deduction; for it is easier to divide into larger parts than smaller ones, and composite things are larger than what they are made from. Next, we must examine which is universal and which is particular. And if both premises have not been supposed, we must put in the other premise ourselves. For sometimes people who put forward a universal premise do not suppose the premise included in it, either in writing or in speech. Or, they do put these premises forward but leave out what they are concluded through and instead ask for other useless things. We must therefore see whether something superfluous has been supposed, and whether one of the necessary premises has been left out, and then we should put in the latter and take away the former until the two premises are reached. For without these, it is not possible to reduce arguments which have been presented through questions in this way.

It is easy to see what is missing from some arguments, then, but it escapes notice in others, and they appear to deduce because something necessary does follow from the things supposed. For example, if it should be supposed that a substance is not done away with by doing away with what is not a substance and that if the things

out of which something is composed are done away with, what is made from them also perishes. For with these supposed, it is necessary for a part of a substance to be a substance; yet it has not been deduced through what was supposed, but instead premises have been left out. Next, if it is necessary that there is an animal if there is a human, and that there is a substance if there is an animal, it is necessary that there is a substance if there is a human, but this has not yet been deduced (for the premises are not related as we have said).

We are deceived in such arguments through the fact that something necessary follows from the suppositions, because a deduction is also something necessary. But the necessary is more extensive than deduction: every deduction is necessary, but not everything necessary is a deduction. Consequently, if something does result when certain things have been supposed, we should not try to reduce it straightaway but instead first get the two premises, then divide them into their terms and put that term said in both the premises as the middle (for the middle must occur in both premises in all of the figures).

So then, if the middle is predicated and a subject of predication, or if it is predicated and something else is denied of it, it will be the first figure; if it is both predicated of something and denied of something, it will be the middle figure; and if others are predicated of it, or one is denied and another is predicated, it will be the last figure. For this is how the middle was in each figure. And similarly if the premises are not universal; for the definition of the middle term will be the same. It is evident, then, that in any argument in which the same thing is not said multiple times there cannot be a deduction; for no middle term has been supposed.

And since we have found which sort of problem is concluded in each figure, and in which one a universal and in what sort a particular, it is evident that we need not look to all the figures, but only to the one appropriate to each problem. For those problems that are concluded in several figures, we will recognize the figure by the position of the middle term.

1.33
Misleading Appearance of Deduction Because of Position of Terms

It often happens, then, that we are deceived about deductions because something necessary follows, as was said earlier, but sometimes it is as a result of the similarity in position of the terms. We must not overlook this. For example, if A is said of B and B of C: it might seem that if the terms are so related there is a deduction, though there is neither anything necessary nor any deduction at all. For let A stand for "always is," B stand for thinkable Aristomenes, and C stand for Aristomenes. Then it is true that A belongs to B, for thinkable Aristomenes always is. But also B belongs to C, for Aristomenes is thinkable Aristomenes. However, A does not belong to C; for Aristomenes is capable of passing away. For a deduction did not

come about with the terms related in this way, and it would be necessary to take premise AB as universal. But this is false, to claim that every thinkable Aristomenes always is, if Aristomenes is capable of passing away. Next, let C stand for Miccalus, B for musical Miccalus, and A for perishing tomorrow. Then, it is true to predicate B of C, for Miccalus is musical Miccalus. But it is also true to predicate A of B, for musical Miccalus may perish tomorrow. However, to predicate A of C is false. So this is in fact the same as the preceding case: for the statement that musical Miccalus perishes tomorrow is not true universally, and if this is not supposed there was not a deduction. This kind of deception, then, arises from a detail, for we are led to agree as if there were no difference between saying that this belongs to that and that this belongs to every that.

1.34
Misleading Appearances of Deduction Because of Setting-Out

But it will often happen that we are misled because the terms in the premise have not been set-out well—for example, if A is health, B stands for illness, C for human. For it is true to say that it is possible for A to belong to no B (for health belongs to no illness), and again that B belongs to every C (for every human is susceptible of illness). It might seem to follow, then, that it is not possible for health to belong to any human. The cause of this is that the terms are not set-out well verbally, since there will not be a deduction if we substitute the predicates corresponding to the states for them, that is, if "healthy" is put in place of "health" and "ill" in place of "illness." For it is not true to say that being healthy cannot belong to someone who is ill. But if this premise is not supposed, a deduction does not come about, unless it is one of being possible. And that is not impossible: for it is possible for health to belong to no human.

Next, a falsehood can happen in the same way in the middle figure. For to no illness, but to every human, does health possibly belong, so that to no human is illness possible. But in the third figure, the falsehood happens with respect to being possible, for it is possible for both health and illness, or both scientific knowledge and ignorance, or in general for contraries to belong to the same thing, but impossible for them to belong to each other. But this is not in agreement with what was said earlier: for when it was possible for several things to belong to the same thing, it was also possible for them to belong to each other.

It is evident, then, that in all these cases the deception results from the setting-out of the terms. For when predicates corresponding to the states are substituted, no falsehood arises. Thus, it is clear that in the case of such premises the predicate corresponding to the state must always be substituted for the state and put as the term.

1.35
Setting-Out a Term without a Name

One should not always seek to set-out terms with a word, for they will sometimes
30 be sentences to which no name has been assigned. For that reason, it is difficult to reduce such deductions, and moreover it will sometimes happen that we are deceived through this sort of search. For example: "Deduction of immediate propositions is possible. Let A be two right angles, B stand for triangle, C stand for isosceles. Then, A belongs to C through B, but A belongs to B through nothing else. For the trian-
35 gle possesses two right angles intrinsically, so that there will be no middle term of AB, although it is demonstrable." For it is evident that we must not always take the middle term as a particular "this" but rather sometimes as an argument, which is just what happens in the example given.

1.36
Alternative Ways Premises May Be Expressed

One must not take the statement that the first belongs to the middle, and this to the
40 extreme, as always implying that they can be predicated of each other, or that the first
48b1 can be predicated of the middle, and it of the last, in the same way (and likewise in the case of not belonging). Instead, in however many ways *be* or *it is true to say this is that* are said of things, we must assume that *belong* is said in that many ways. Take as an example the statement that there is a single science of contraries. For let A be
5 there being a single science, and let B stand for things contrary to each other. Then, A belongs to B, not in the sense that contraries are a single science of them,[77] but because it is true to say of them that there is a single science of them.

10 Sometimes it happens that the first is said of the middle but the middle is not said of the third. For example, if theoretical wisdom is a science and theoretical wisdom is of the good, the conclusion is that a science is of the good. (So the good is not a science, but theoretical wisdom is a science.) And sometimes, the middle is said of the
15 third, but the first is not said of the middle. For example, if there is a science of every quality or contrary, and the good is both a contrary and a quality, the conclusion is that there is a science of the good (but the good is not a science, nor is a quality or a contrary, though the good is these). And it is possible for neither the first to be said of
20 the middle nor this of the third, with the first sometimes being said and sometimes not being said of the third. For example, if there is a kind of that of which there is a science, and there is a science of the good, the conclusion is that there is a kind of the good, although nothing is predicated of anything. And if that of which there is
25 a science is itself a kind, and there is a science of the good, the conclusion is that the

77. Reading τὸ μίαν εἶναι αὐτῶν ἐπιστήμην. This is meant to be nonsense.

good is a kind: so the first [extreme] is predicated of the [last] extreme, but the terms are not said of each other.

We must take it in the same way in the case of not belonging. For "this does not belong to that" does not always signify that this is not that, but sometimes this is not of that or this is not to that. For example, "There is no movement of a movement or coming-to-be of a coming-to-be, but there is a coming-to-be of pleasure; therefore, pleasure is not a coming-to-be"; or again, "There is a sign of laughter, but there is no sign of a sign; consequently, laughter is not a sign." Similarly in other cases in which a problem is done away with through the kind being said of itself[78] in a way. Next, "The opportune moment is not the time needed, for there is an opportune moment for a god, but not a time needed, because nothing is profitable for a god." Opportune moment, time needed, and god should be put as terms and the premise should be supposed in accord with the inflections of the words. For we say this unconditionally about all cases: terms must always be put in accord with their nominative forms (as "man" or "good" or "contraries," not "man's" or "of the good" or "of contraries"), while premises must be taken in accord with the inflection of each term. For it might be "to this" (as "equal"), or "of this" (as "double"), or "this" in the accusative case (as "hitting" or "seeing"), or "this" in the nominative (as "a human is an animal"), or if the word is inflected in some other way in the premise.

1.37
A Note on the Many Senses of "Belongs To"

"This belongs to that" and "this is true of that" should be taken in as many ways as the ways in which predications have been divided,[79] and these either in some way or unconditionally and either simple or compound; and similarly also with not belonging. (These things must be investigated and better determined.)

1.38
Reduplicated Terms in Premises

Anything reduplicated in the premises is to be put with the first extreme, not with the middle term. I mean, for example, if there is a deduction that of justice there is knowledge that it is good, "that it is good" (or "insofar as it is good") should be put with the first extreme. For let A be knowledge that it is good, B stand for good, C stand for justice. Then it is true to predicate A of B: for there is knowledge that it is good of something that is good. But it is also true to predicate B of C: for justice

78. Reading αὐτὸ.
79. 48^b2–5.

is precisely something good. In this way, then, an analysis results. However, if "that it is good" is put with B, there will not be one, for A will be true of B, but B will not be true of C (for to predicate "good that it is good" of justice is false—or rather, unintelligible). And similarly if it is proved that what is healthy is knowable insofar as it is good, or a goat-stag insofar as non-existent, or that a human is capable of passing away insofar as it is perceptible. For in all these cases of extra predication, the reduplication should be put with the [first] extreme.

The setting of the terms is not the same when something is deduced unconditionally and when it is deduced as something that is such-and-such,[80] or in some respect, or in some way.[81] (I mean, for example, when something good is proved to be knowable and when it is proved of [the] knowable that it is good.) Instead, if it has been proved to be knowable unconditionally, then so-and-so should be taken as the middle term, whereas if it has been proved to be knowable that it is good, something that is such-and-such should be taken. For let A be knowledge that it is so-and-so, let what B stands for be something that is such-and-such, and let C stand for good. Then it is true to predicate A of B: for there was [by assumption] knowledge of what is such-and-such that it is so-and-so. But it is also true to predicate B of C (for what C stands for is something that is such-and-such), so that also A of C. Therefore, there will be knowledge of what is good that it is good (for "such-and-such" is a sign for the thing's special substance). But if being so-and-so had been put as the middle term, and "what is" unconditionally rather than "what is so-and-so" had been added to the [first] extreme, there would not have been a deduction that there is knowledge of what is good that it is good, but rather that it *is* (that is to say, if A stands for knowledge that it is, B stands for being, C stands for good). It is evident, then, that the terms should be taken in this way in particular deductions.

1.39
Use Names Rather Than Accounts in Premises

One should substitute things that have the same meaning for each other (names in place of names, accounts in place of accounts), whether a name or an account, and always take the name instead of the account; for the setting-out of terms will be easier. For example, if there is no difference between saying that the supposable is not the kind of the believable and that what is believable is not precisely a certain sort of supposable (for what is signified is the same), "supposable" and "believable" should be put as terms in place of the account stated.

80. Reading τι τόδε.
81. *SE* 166b37–167a20.

1.40
A Note on "Good" and "the Good"

Since it is not the same thing for pleasure to be *a* good and for pleasure to be *the* good, the terms should not be put in the same way. Rather, if the deduction is that pleasure is *the* good, "the good" should be put as the term, while if the deduction is that pleasure is *a* good, "a good" should be put. And this way also in the other cases.

1.41
Issues Concerning "Belongs"; No Absurdity from Setting-Out

It is not the same thing, either in being or in speaking, [to say] that what B belongs to, A belongs to all of, and to say that what B belongs to all of, A also belongs to all of. For nothing prevents B from belonging to C, but not to every C. For example, let B be beautiful and C white. Then, if beautiful belongs to something white, it is true to say that beautiful belongs to the white, but perhaps not to everything white. So then if A belongs to B, but not to everything B is said of, whether B belongs to *every* C, or merely belongs to it, not only is it not necessary for A to belong to *every* C, it is not even necessary for it to belong at all. But if it belongs to everything B is truly said of, it will follow that whatever B is said of all of, A will be said of all of that. However, if A is said of whatever B is said of all of, nothing prevents B from belonging to C while A does not belong to every C, or even does not belong to C at all. So putting it in three terms, it is clear that "everything B is said of, A is said of" is this: "whatever things B is said of, A is also said of all those." And if B is said of all of something, A is likewise [said of all of it], but if B is not said of all of something, it is not necessary that A be said of all of it.

One should not think that any absurdity results from setting-out. For we do not make any use of there being a certain particular thing; instead, it is like someone who, in giving a proof, says that this line is a foot long, straight, and breadthless (though it is[82] not) but does not use these as something to deduce from. For to speak generally, if something is not related as whole to part, with something else related to it as part to whole, the person who proves does not prove from such a thing, so that neither does any deduction come about from it. We use setting-out in the same way as when we tell[83] a learner to "perceive." For it is not as if the **50^{a}1** conclusion could not be demonstrated without such things, as it is in the case of the premises a deduction is from.

82. Reading οὖσαν.
83. Reading μανθάνοντα λέγοντες.

1.42
Not All the Conclusions in the Same Deduction Are through a Single Figure

Let us not overlook the fact that not all the conclusions in the same deduction are through a single figure, but rather one is through this figure and one is through that one. Clearly, then, analyses must also be produced in this way. And since not every problem is proved in all the figures and instead they have been arranged according to each figure, it is evident from the conclusion in which figure we should seek.

1.43
On Deductions Attacking a Definition

In arguments attacking a definition that happen to draw a conclusion about one of the terms in the definition, one should put what the conclusion was drawn about as a term rather than the whole account (for confusion is less likely to result because of length). For example, if someone proved that water is a drinkable liquid, drinkable and water should be put as the terms.

1.44
Arguments from an Assumption Not to Be Reduced

Moreover, we should not try to reduce deductions from an assumption; for it is not possible to reduce them from the premises supposed. For these arguments were not proved through a deduction, but instead all of them were assented to on the basis of an agreement. For example, if someone, making the assumption that if there is not one capacity for contraries, there is not one science of them either, argued next that there is not one[84] capacity for [every pair of] contraries—for example, in the case of what makes healthy and what makes unhealthy (for the same thing would be at the same time healthy and unhealthy). A proof has then been presented that there is not one capacity for every [pair of] contraries, but it has not been proved that there is not one science of them. And yet it is necessary to agree to this, although not on the basis of a deduction but on the basis of an assumption. This argument cannot be reduced, then, but that there is not a single capacity can be, for the latter was perhaps a deduction but the former was an assumption.

It is likewise with deductions that conclude through the impossible, for these arguments also cannot be analyzed; however, the part that is the reduction to the impossible can be analyzed (for that is proved by a deduction), while the other part

84. Reading μία.

cannot be (for that is concluded from an assumption). These deductions differ from the ones discussed previously because in the earlier ones, it was necessary for [the opponent] to agree in advance whether he is going to concur (that is, concur that if it is proved that there is a single capacity of contraries, the science of them is also the same). In these latter cases, however, people concur even without having made an agreement in advance because the falsehood is obvious (for example, that when it is supposed that the diagonal is commensurable odd numbers are equal to even ones).

Many other deductions are also brought to a conclusion from an assumption, and these must be examined and accurately marked out. We will say later[85] what the differences among these are and in how many ways something can be deduced from an assumption. But for the present, let this much be evident to us: that it is not **$50^{b}1$** possible to analyze these sorts of deductions into the figures. (And we have explained due to what cause this is so.)

1.45
Reducing Deductions from One Figure to Those in Another

For those problems that are proved in several figures, if they have been deduced in one of those figures, it is possible to reduce the deduction to the other figure. For example, a privative deduction in the first figure can be reduced to the second and a privative deduction in the middle figure reduced to the first. Not all of the deductions can be reduced, however, but only some. This will be evident in what follows. For if A belongs to no B and B to every C, A belongs to no C: in this way, then, it is the first figure, but if the privative is converted it will be the middle figure (for B belongs to no A but to every C). And similarly if the deduction is not universal but particular—for example, if A belongs to no B but B belongs to some C (for when the privative is converted it will be the middle figure). The universal deductions in the second figure can be reduced to the first figure, but only one of the particular deductions can be. For let A belong to no B but to every C. Then when the privative is converted it will be the first figure (for B will belong to no A and A to every C). But if the positive is with B and the privative with C, C must be put as the first term. For this belongs to no A and A to every B, so that C belongs to no B, and therefore neither does B belong to any C (for the privative converts). And if the deduction is particular, when the privative is with the major extreme, the deduction can be reduced to the first figure, as when A belongs to no B and to some C. For when the privative is converted, it will be the first figure (for B belongs to no A and A to some C). But when it is the positive premise, the deduction cannot be analyzed (for example, if A belongs to every B and not to every C: for AB does not admit of conversion, nor would there be a deduction if it did).

85. Aristotle does not address this topic in any surviving treatise.

Next, the deductions in the third figure cannot all be analyzed into the first, but those in the first can all be analyzed into the third. For let A belong to every B and B to some C. Then, since the particular positive converts, C will belong to some B. But A belonged to every B, so that it becomes the third figure. And likewise if the deduction is privative (for the particular positive converts, so that A will belong to no B and C will belong to some).

51^a1 Only one of the deductions in the last figure is not analyzed into the first (the one when the privative is not put as universal), but all the others are so analyzed. For let A and B be predicated of every C. Then, C will convert partially in relation to each term. Therefore, it will belong to some B, so that it will be the first figure (if A belongs to every C and C to some one of the Bs[86]). And if A belongs to every C and B to some C, the argument is the same. For C converts in relation to B. But if B belongs to every C and A to some C, B must be put as the first term (for B belongs to every C and C to some A, so that B belongs to some A; and, since the particular converts, A will also belong to some B). If the deduction is privative, then, when the terms are universal it must be supposed in the same way. For let B belong to every C and A to none; then, C will belong to some B and A to no C, so that C will be the middle term. Similarly if the privative is universal and the positive is particular (for A will belong to no C and C to some of the Bs). However, if the privative is supposed as particular, no analysis will be possible (that is, if B belongs to every C and A does not belong to some C). For when BC is converted both the premises will be particular.

It is also evident that in order to analyze the figures into each other, the premise with the minor extreme must be converted in both the figures; for it was when this premise was substituted that the transition to the other figure took place.

One of the deductions in the middle figure can be analyzed into the third and the other cannot be. For when the universal is privative, the deduction can be analyzed: if A belongs to no B and to some C, both convert alike in relation to A, so that B belongs to no A and C to some (the middle, therefore, is A). But when A belongs to every B and does not belong to some C, an analysis is not possible (for neither of the premises resulting from the conversion is universal).

The deductions from the third figure can also be analyzed into the middle if the privative is universal, that is, if A belongs to no C and B belongs to some or to every C (for C will also belong to no A and to some B). But if the privative is particular, the deduction cannot be analyzed; for a particular negative does not admit of conversion.

It is evident, then, that the deductions that are not analyzed in these figures are the same ones that were also not analyzed into the first, and that when deductions **51^b1** are reduced to the first figure, these deductions alone are brought to a conclusion through the impossible.

From what has been said, then, it is evident how one must reduce deductions, and also evident that the figures are analyzed into each other.

1.46
"Not to Be This" and "to Be Not This" Distinguished

It makes a certain difference in establishing and disestablishing whether one thinks that "not to be this" and "to be not this" signify the same thing or different things (for example, "not to be white" and "to be not white").[87] For these do not signify the same thing, nor is "to be not white" the negation of "to be white" (instead, "not to be white" is). The argument for this is as follows: "can walk" has the same relationship to "can not walk" as "is white" has to "is not white," or as "knows the good" has to "knows the not good." For "knows the good" is no different from "is knowing the good," and "can walk" is no different from "is one who can walk."[88] Consequently, their opposites, "can not walk" and "is one who can not walk," are also no different. Therefore, if "is not one who can walk" does signify the same thing as "is one who can not walk" (or "can not-walk"[89]), these can even belong to the same thing at the same time (for the same person can walk and not-walk, and is knowledgeable of the good and the not good): but an opposite affirmation and negation do not belong at the same time to the same thing. Therefore, just as "not to know the good" and "to know the not good" are not the same, neither are "to be not good" and "not to be good" the same: for with terms related in the same way, if those in one pair are different, those in the other pair are also different.

Nor are "to be not equal" and "not to be equal" the same. For there is some subject for "to be not equal" (that is, whatever it is that is unequal) but there is not any subject for the other. This is why not everything is equal or unequal, though everything is equal or not equal.

Next, "it is a not white log" and "it isn't a white log" do not belong to things together. For if a log is not white it will be a log, whereas it is not necessary that what isn't a white log is a log.

Consequently, it is evident that "it is not good" is not the negation of "it is good."[90] Therefore, if either the affirmation or the negation is true of every single thing, then

87. Aristotle's examples sometimes depend on distinguishing whether "not" negates a whole sentence or a single word (in modern terminology, its scope). In Greek, that difference is expressed entirely by word order, but this cannot be reproduced in English. Instead, a hyphen is sometimes used to connect "not" with the expression it modifies.

88. Literally, "is being-able-to walk." English "can" has no present participle; "is one who can walk" is a workaround.

89. Greek has two words for "not": *ou* and *mê*. Usually, *mê* is used with infinitives, but up to this point in the argument Aristotle has used *ou* with "to walk" (*badizein*) as well as with "white" and "knows." Here he appears to take note that *ou badizein* is not quite normal Greek and gives the usual *mê badizein* as an alternative. To reflect this, *ou badizein* is translated as "not walk" and *mê badizein* as "not-walk."

90. These examples rely on a distinction it is impossible to reproduce in ordinary English: *ouk esti leukon*—word for word "not it is white"—is the negation of "it is white" and corresponds to English "it isn't white," but *estin ou leukon* (word for word "it is not white") *can* be understood

if "it is not-good" is not a negation it is clear that it is a sort of affirmation. But there is a negation of every affirmation. Therefore, the negation of this affirmation is "it isn't not-good."

They stand in this order in relation to each other. Let A stand for "to be good," B stand for "not to be good," C stand for "to be not-good" (which is below B), and D stand for "not to be not-good" (which is below A). Either A or B will belong to everything but not at the same time to the same thing, and also either C or D will belong to everything and not both to the same thing. And it is necessary for B to belong to everything to which C belongs: for if it is true to say that it is not-white, it is also true to say that it isn't white (for it is impossible to be white and to be not-white at the same time, or to be a not-white log and to be a white log), so that if the affirmation does not belong, the negation will. But C does not always belong to B (for what is not a log at all will not be a not-white log either). Therefore, in reverse order, D belongs to everything A belongs to: for either C or D belongs to everything, and since it is not possible to be at the same time not-white and white, D will belong (for of what is white it is true to say that it isn't not-white). But A will not be true of every D; for it is not true to say A (that it is a white log) of what is not a log at all. Consequently, it is true to say D of it, but it is not true to say A (that it is a white log). It is also clear that it is not possible for A and C to belong to anything the same but that it is possible for B and D to belong to the same thing.

Privations also have the same relationship to their predications when put in this arrangement. Let A stand for equal, B stand for not equal, C stand for unequal, D stand for not unequal.

In the case of a group of things, where the same term belongs to some of them and not to others, the negation might similarly be true either because they are not all white or because each of them is not white, though it is false that each is not white or that all are not white. In the same way, the negation of "every animal is white" is not "every animal is not white" (for both are false), but "not every animal is white."

And since it is clear that "it is not white" and "it isn't white" signify different things, and that one is an affirmation and the other a negation, it is evident that the way of proving each is not the same (that is, proving that whatever is an animal is not white, or that it is possible for it not to be white, and proving that it is true to call it not-white—for that is to be not-white). But "it is true to call it white" and "[it is true to call it] not-white" *are* proved in the same way, for both are proved by establishing through the first figure. For "true" is ordered in the same way as[91] "is": the negation of "it is true to call it white" is not "it is true to call it not white" but

---

as saying of something that it has the affection of being "not white." This is represented in the translation with a hyphen between "not" and the following term ("it is not-white"), but in Greek the difference is entirely in the word order.

91. I.e., in Greek the word order is the same: the negation of "it is true to call it white" is, word for word, "not it is true to call it white."

instead "it isn't true to call it white." So if [the thing to be proved] is[92] "it is true to say that whatever is a human is musical" or "not musical," then suppose that whatever is an animal is musical or is not musical, and it has been proved. But "whatever is a human is not musical" is proved by disestablishing it in accordance with the three ways stated.

In general, whenever A is so related to B that it is not possible for them to belong to the same thing at the same time but necessary for one or the other of them to belong to everything, and C and D, in turn, are likewise related, and A follows C and does not convert with it, D will also follow B and will not convert with it. Also, it is possible for A and D to belong to the same thing but not possible for B and C to.

First, then, it is evident from the following argument that D follows B. Since one or the other of CD belongs to everything of necessity, but it is not possible for C to belong to what B does (because C brings A along with it, and it is not possible for A and B to belong to the same thing), it is evident that D will follow B. Next, since C does not convert with A, but either C or D belongs to everything, it is possible for A and D to belong to the same thing. However, this is not possible for B and C, because A follows along with C (for something impossible results). It is evident, then, that B does not convert with D either, since it is possible for D and A to belong at the same time.

Sometimes, we are also deceived in this sort of arrangement of terms because of not correctly taking opposites one or the other of which must necessarily belong to everything—for example, if it is not possible for A and B to belong to the same thing at the same time, but it is necessary for one of them to belong to what the other does not, and next C and D are likewise related, and A follows everything C belongs to. For it will follow that B belongs of necessity to whatever D does, and that is precisely what is false. For [we might reason as follows:] "Take F to stand for the negation of AB, and next take H to stand for the negation of CD. Then it is necessary for either A or F to belong to everything (for either the affirmation or the negation does). Next, either C or H belongs to everything (for they are an affirmation and negation). But A was assumed to belong to everything C belongs to. Consequently, H belongs to everything F does. Next, since one or the other of F, B belongs to everything, and one or the other of H, D likewise, and H follows F then B will also follow D (for we know this). Therefore, if A belongs to C, B also belongs to D." But this is incorrect, for the consequence was in reverse order for terms related in this way. For it is surely not necessary for either A or F to belong to everything, nor necessary for either F or B to (for F is not the negation of A, since "not good" is the negation of "good" but "not good" is not the same as "neither good nor not good"). And in the same way also in the case of C, D; for the negations that were supposed are two.

92. Reading ἔστι.

BOOK 2

2.1
Additional Conclusions That Follow in Deductions

We have already gone through the number of figures a deduction comes about in, and the sorts and number of premises it is through, and when and why this occurs; and in addition what things one must look at when disestablishing or establishing, and how one must search for premises concerning whatever is proposed [for proof], in accord with any methodical inquiry whatever, and finally the route through which we may obtain the starting-points concerning each subject.

But since some deductions are universal and others are particular, all the universals always deduce more than one thing; among particular deductions, the positive ones deduce more than one thing, but negatives deduce only the conclusions. For the other premises convert, but the privative [particular] premise does not convert, and the conclusion is one thing predicated of another; consequently, the other deductions deduce something additional. For example, if A has been proved to belong to every or to some B, it is also necessary that B belongs to some A, and if A belongs to no B, neither does B belong to any A (and that is a different conclusion from the previous one). However, if A does not belong to some B, it is not also necessary that B does not belong to some A, since it is possible for it to belong to all.

This cause, then, is common to all deductions, both universal and particular. However, something different can be said for the universal ones: whatever terms are under either the middle or the conclusion, there will be the same deduction for them all if the former are put under the middle or if the latter are put under the conclusion. For example, if conclusion AB is [deduced] through C, then whatever terms are below B or C, it will be necessary that A is said of all of them. For if D is in B as a whole, and B in A, D will also be in A. Next, if E is in C as a whole, and C in A, E will also be in A. And similarly if the deduction is privative.

But in the second figure, we can deduce only what is below the conclusion—for example, when A belongs to no B and to every C (the conclusion is that B belongs to no C). If D is below C, it is evident that B will not belong to it. However, it is not clear by means of the deduction that it does not belong to those below A. To be sure, B does not belong to E if E is below A. But what was proved through the deduction was that B belongs to no C, while that B does not belong to A was supposed as undemonstrated; consequently, that B does not belong to E does not follow through the deduction. And in the case of particular deductions, no necessary result will be possible for terms below the conclusion (for a deduction does not come about when this premise is taken as particular). One will be possible for all those below the middle term, except that it does not result by means of the [same] deduction. For example, if A belongs to every B and B to some C, there will not be a deduction for what is put

below C, but there will be one for what is put below B, although it is not through the deduction already formed.

And similarly in the case of the other figures: there will not be a deduction for something below the conclusion, but there will be one for what is below the other term, except that it results not through the deduction, but in the way that those below the middle were also proved from the undemonstrated premise in the case of the universals. Consequently, either there will not be a deduction in the former case, or there will also be one in the latter case. **53^b1**

2.2
True Conclusions from False Premises: First Figure

Matters may be such that the premises through which a deduction comes about are true, or that they are false, or that one premise is true and the other false. But the conclusion is of necessity either true or false. From true premises, then, it is not possible to deduce a false conclusion, but it is possible to deduce a true conclusion from false premises (except that it is not a deduction of the why but of the that, for a deduction of the why is not possible from false premises). The cause due to which this is so will be explained in what follows.

First, then, it is clear from the following that it is not possible to deduce a false conclusion from true premises. For if it is necessary that B is when A is, when B is not it is necessary that A is not. Therefore, if A is true, it is necessary that B is true, or else it will follow that the same thing both is and is not at the same time: but that is impossible.

But one must not think that, because A is set-out as a single term, it is possible for something to follow of necessity when a single thing is so; for it cannot. For what follows of necessity is the conclusion, and the fewest things through which this comes about is three terms and two intervals (that is, premises). So, then, if it is true that A belongs to everything B belongs to, and B to what C belongs to, it is necessary for A to belong [to what C belongs to], and this cannot be false (for the same thing would belong and not belong at the same time). Therefore, A is put as one thing, the two premises supposed together. It is similar in the case of privative deductions. For it is not possible to prove a false conclusion from true premises.

It is possible, however, to deduce a truth from false premises, either when both premises are false or when only one is (this cannot be either premise indifferently, if it is taken to be wholly false, but only the second; however, if it is not taken as wholly false, it can be either premise). For let A belong to the whole of C and to none of the Bs,[93] and B belong to no C. (This is possible: for example, animal does not belong to any stone, nor stone to any human.) Then, if A is supposed to belong to every B and

93. Reading τῶν B.

B to every C, A will belong to every C; consequently, from premises both of which are false the conclusion is true (for every human is an animal). The privative deduction is likewise. For it is possible for neither A nor B to belong to any C and yet A to belong to every B—for example, if the same terms are supposed but human is put as the middle (for neither animal nor human belongs to any stone, but animal belongs to every human). Thus, if one takes one term to belong to none of what it does belong to and the other to belong to all of what it does not belong to, the conclusion will be true from premises both of which are false. This can also be proved in the same way if each premise is taken to be false in part.

But if only one premise is put as false, then when the first premise (that is, premise AB) is wholly false the conclusion cannot be true, but when premise BC is wholly false it can be. (By "wholly false" I mean the contrary premise, that is, if what belongs to none is supposed to belong to every, or if what belongs to every is supposed to belong to none.) For let A belong to no B and B to every C. If I take premise BC as true and AB as wholly false (that is, take A to belong to every B), it is impossible for the conclusion to be true (for A did not belong to any of the Cs, if it belongs to none of what B belongs to and B belongs to every C). And similarly, if A belongs to every B and B to every C, and BC was supposed as a true premise but AB as a wholly false one (that is, A was taken to belong to none of that to which B belongs), the conclusion will be false: for A will belong to every C, since A belongs to everything to which B belongs and B to every C. It is evident, then, that when the first premise is supposed as wholly false (whether it is affirmative or privative) and the other premise as true, the conclusion cannot be true.

However, when the first premise is supposed as not wholly false, the conclusion may be true. For if A belongs to every C and to some B, and B belongs to every C (for example, animal belongs to every swan and to something white, and white belongs to every swan), if A is supposed to belong to every B and B to every C, A will belong to every C truly (for every swan is an animal). And similarly if AB is privative. For it is possible for A to belong to some B and to no C and for B to belong to every C—for example, animal belongs to something white and to no snow, and white belongs to all snow. Therefore, if A is taken to belong to no B and B to every C, A will belong to no C.

But if premise AB is supposed as wholly true and premise BC as wholly false, there will be a true deduction. For nothing prevents A from belonging to every B and every C and yet B belonging to no C—for example, such forms of the same kind as are not under each other. For animal belongs both to horse and to human, but horse belongs to no human. So, if A is taken to belong to every B and B to every C, the conclusion will be true with premise BC being wholly false. And similarly if premise AB is privative. For it is possible for A to belong neither to any B nor to any C, nor B to any C, as a kind does to forms from another kind. For animal belongs neither to music nor to medicine, nor does music belong to medicine. Therefore, if A is supposed to belong to no B and B to every C, the conclusion will be true. And

if premise BC is not false wholly, but only in part, the conclusion will also be true in this way. For nothing prevents A belonging to the whole both of B and of C and yet B belonging to some C, as a kind does to a form and its difference. For animal belongs to every human and to everything that walks, but human belongs to something, not everything, that walks. Therefore, if A is assumed to belong to every B and B to every C, A will belong to every C, which was true. And similarly if premise AB is privative. For it is possible for A to belong neither to any B nor to any C but yet for B to belong to some C, as a kind does to a form and a difference from another kind. For animal belongs neither to any wisdom nor to any theoretical science, but wisdom belongs to some theoretical science. If, then, A is taken to belong to no B and B to belong to every C, A will belong to no C (and this was true).

In the case of particular deductions, it is possible for the conclusion to be true when the first premise is wholly false and the other premise true, or when the first premise is false in part and the other premise is true, or when the first premise is true and the other premise false in part, or when both premises are false. For nothing prevents A belonging to no B and to some C and B belonging to some C, as animal belongs to no snow but to something white and snow to something white. Therefore, if snow is put as the middle term and animal as the first, and A is supposed to belong to the whole of B and B to some C, premise AB is wholly false, premise BC is true, and the conclusion is true.

And similarly if premise AB is privative. For it is possible for A to belong to the whole of B and not to belong to some C, and yet for B to belong to some C, as animal belongs to every human but does not follow something white and human belongs to something white. Consequently, putting human as the middle term, if A is supposed to belong to no B and B to some C, the conclusion will be true when premise AB is wholly false. The conclusion can also be true if premise AB is false in part. For nothing prevents A from belonging both to some B and to some C and B belonging to some C, as animal belongs to something beautiful and to something large and beautiful belongs to something large. Therefore, if A is supposed to belong to every B and B to some C, premise AB will be false in part, premise BC true, and the conclusion true. And similarly also when premise AB is privative (the terms will be the same and positioned likewise for the demonstration). **55^{a}1**

Next, if premise AB is true and premise BC false, the conclusion can be true. For nothing prevents A from belonging to the whole of B and to some C and B belonging to no C, as animal belongs to every swan and to something black and swan belongs to nothing black. Consequently, if A is supposed to belong to every B and B to some C, the conclusion will be true when BC is false. And similarly when premise AB is taken as privative. For it is possible for A to belong to no B and not belong to some C and yet for B to belong to no C, as a kind does to a form from another kind and to a coincident of its own forms. For animal belongs to no number and to something white, and number to nothing white. Therefore, if number is put as the middle term

and A is supposed to belong to no B and B to some C, A will not belong to some C (which was [supposed to be] true), and premise AB is true while premise BC false.

And if premise AB is false in part and premise BC is also false, the conclusion can be false. For nothing prevents A from belonging both to some B and to some C and B to no C—for example, if B is contrary to C and both are coincidents in the same kind. For animal belongs to something white and to something black, but white belongs to nothing black. Therefore, if A is supposed to belong to every B and B to some C, the conclusion will be true. And likewise if premise AB is supposed as privative (the same terms, arranged likewise, may be put for the demonstration).

The conclusion can also be true when both premises are false. For it is possible for A to belong to no B and to some C and yet B to belong to no C, as a kind does to a form from another kind and to a coincident of its own forms. For animal belongs to no number and to something white, and number belongs to nothing white. Therefore, if A is supposed to belong to every B and B to some C, the conclusion is true but the premises are both false. And similarly when premise AB is privative. For nothing prevents A belonging to the whole of B and not belonging to some C and B not belonging to any C, as animal belongs to every swan and does not belong to something black and swan belongs to nothing black. Consequently, if A is supposed to belong to no B and B to some C, A will not belong to some C (the conclusion, then, is true, and the premises are false).

2.3
True Conclusions from False Premises: Second Figure

In the middle figure it is possible to deduce a true conclusion through false premises in all ways: when both premises are supposed as wholly false, or when either one is supposed as false in part, or when one as true and the other as [wholly] false (no matter which one is put as false), {or if both are false in part, or if one is simply true and the other false in part, or if one is wholly false and the other in part true,}[94] in the case of universal as well as particular deductions.

For if A belongs to no B and to every C, as animal belongs to no stone and to every horse, if the premises are put contrariwise and A is supposed to belong to every B and to no C, the conclusion will be true from wholly false premises. And similarly if A belongs to every B and to no C (for it will be the same deduction).

And again if one premise is wholly false and the other wholly true. For nothing prevents A from belonging both to every B and to every C and yet B to no C, as a kind does to forms that are not under each other. For animal belongs both to every horse and to every human, and no human is a horse. Therefore, if animal is supposed to belong to all of one and none of the other, one premise will be wholly false, the

94. The bracketed text has been rejected by editors as an inaccurate later addition.

other premise will be wholly true, and the conclusion will be true, no matter which one the privative is put in relation to.

Also, if one premise is false in part and the other premise wholly true. For it is possible for A to belong to some B and to every C and yet for B to belong to no C, as animal belongs to something white and to every raven, and white to no raven. If, then, A is supposed to belong to no B and to the whole of C, premise AB is false in part, premise AC is wholly true, and the conclusion is true. And likewise when the privative is put the other way around (for the demonstration is through the same terms).

Also, if the affirmative premise is false in part and the privative premise wholly true. For nothing prevents A from belonging to some B and not belonging to the whole of C, and B belonging to no C, as animal belongs to something white and to no pitch, and white to no pitch. Thus, if A is supposed to belong to the whole of B and to no C, premise AB is false in part, premise AC is wholly true, and the conclusion is true.

Also, if both premises are false in part the conclusion can be true. For it is possible for A to belong both to some B and to some C and for B to belong to no C, as animal belongs both to something white and to something black and white belongs to nothing black. Therefore, if A is supposed to belong to every B and to no C, both premises **56^a1** are false in part but the conclusion is true. And similarly if the privative premise is put the other way around ([the proof is] through the same terms).

This is also evident in the case of particular deductions. For nothing prevents A belonging to every B and to some C and B not belonging to some C (for example, animal belongs to every human and to something white, but human can fail to belong to something white). Therefore, if it is supposed that A belongs to no B and belongs to some C, the universal premise is wholly false, the particular premise is true, and the conclusion is true. And likewise also if premise AB is supposed as affirmative. For it is possible for A to belong to no B and not to some C and for B not to belong to some C (for example, animal belongs to nothing inanimate and not[95] to something white, but inanimate may fail to belong to something white). Therefore, if A is supposed as belonging to every B and not belonging to some C, premise AB (the universal premise) is wholly false, premise AC is true, and the conclusion is true.

And [the conclusion may be true] when the universal premise is put as true and the particular premise as false. For nothing prevents A following neither any B nor any C but yet B not belonging to some C, as animal belongs to no number or anything inanimate and number does not follow something inanimate. Then, if A is put as belonging to no B and to some C, the conclusion will be true, as will the universal premise, but the particular premise will be false.

And likewise when the universal premise is put as affirmative. For it is possible for A to belong to the whole both of B and of C, but yet for B not to follow some C, as

95. Reading λευκῷ δὲ τινὶ οὔ.

a kind in relation to its form and the difference. For animal follows every human and follows walking as a whole, but human does not follow everything walking. Consequently, if A is supposed as belonging to the whole of B and not belonging to some C, the universal premise is true, the particular premise is false, and the conclusion is true.

And it is evident that a true conclusion is also possible from premises that are both false, since it is possible for A to belong to the whole of B and of C, but yet for B not to follow some C. For if A is supposed to belong to no B and to some C, both premises are false but the conclusion is true. And similarly if the universal premise is positive and the particular premise is privative. For it is possible for A to follow no B and every C and B not to belong to some C (as animal follows no science and every human and science does not follow every human). Therefore, if A is supposed to belong to the whole of B and not to follow some C, the premises are false but the conclusion is true.

2.4
True Conclusions from False Premises: Third Figure

There can also be a true conclusion through false premises in the last figure when both premises are wholly false, or when each premise is false in part, or when one premise is wholly true and the other false, or when one is false in part and the other wholly true, or the reverse, or in whatever other ways it is possible to substitute premises. For nothing prevents neither A nor B belonging to any C and yet A belonging to some B. For example, neither human nor walking follows anything inanimate and yet human belongs to something walking. If A and B are taken to belong to every C, then, the premises are wholly false but the conclusion true. And likewise also when one premise is privative and the other is affirmative. For it is possible for B to belong to no C and A to every C and for A not to belong to some B (for example, black belongs to no swan, animal to every swan, and animal does not belong to everything black). Consequently, if B is supposed to belong to every C and A to none, A will not belong to some B. The conclusion is then true but the premises are false.

The conclusion can also be true if each premise is false in part. For nothing prevents both A and B belonging to some C, and A belonging to some B (for example, white and beautiful belong to some animal and white belongs to something beautiful). Therefore, if A and B are put as belonging to every C, the premises are false in part and the conclusion is true. And similarly when premise AC is put as privative. For nothing prevents A not belonging to some C, B belonging to some C, and A not belonging to every B (as white does not belong to some animal, beautiful does belong to some animal, and white does not belong to everything beautiful). Consequently, if A is supposed to belong to no C and B to every C, both the premises are false in part and the conclusion is true.

And likewise when one premise is taken as wholly false and the other as wholly true. For it is possible for both A and B to follow every C but yet for A not to belong to some B (for example, animal and white both follow every swan, and yet animal does not belong to everything white). Therefore, putting these as the terms, if B is supposed to belong to the whole of C, and A not to belong to the whole of it, premise BC will be wholly true, premise AC wholly false, and the conclusion true. And similarly if BC is false and AC true (for the terms for the demonstration are the same). Also, if both premises are supposed as affirmative. For nothing prevents B following every C, A not belonging to it as a whole, and A belonging to some B (for example, animal belongs to every swan, black to no swan, and black belongs to some animal). Consequently, if A and B are supposed to belong to every C, premise BC is wholly true, premise AC wholly false, and the conclusion true. And similarly when premise AC is supposed as true (for the demonstration is through the same terms).

Next, when one premise is wholly true and the other is false in part. For it is possible for B to belong to every C, for A to belong to some C, and for A to belong to some B (for example, two-footed belongs to every human, beautiful does not belong to every human, and beautiful belongs to something two-footed). So then, if both A and B are supposed to belong to the whole of C, premise BC is wholly true, premise AC is false in part, and the conclusion is true. And similarly when premise AC is taken as true and premise BC as false in part (for the demonstration will be with the same terms transposed). And when one premise is privative and the other is affirmative. For since it is possible for B to belong to the whole of C, A to some C, and—with the terms so related—for A not to belong to every B, therefore if B is taken to belong to the whole of C and A to none, the privative premise is false in part and the other premise is wholly true, as is the conclusion. Next, since it has been proved that when A belongs to no C and B belongs to some C it is possible for A not to belong to some B, it is evident that when premise AC is wholly true and premise BC false in part, it is also possible for the conclusion to be true. For if A is supposed to belong to no C and B to every C, premise AC is wholly true and premise BC false in part.

It is also evident that in particular deductions a true conclusion can be deduced through false premises in all ways. For the same terms are to be taken as when the premises are universal: the positive terms in positive deductions, the privative terms in privative deductions (for it makes no difference with respect to the setting-out of the terms whether we take what belongs to none to belong to every or take what belongs to some to belong universally). And similarly for the privatives.

It is evident, then, that if the conclusion is false, it is necessary for either all or some of the premises that the argument depends on to be false, but when the conclusion is true, it is not necessary either for one or for all of the premises to be true; instead, it is equally possible, when none of the premises in the deduction is true, for the conclusion to be true, although not of necessity. The cause of this is that when two things are so related to each other that if one is, the other of necessity is, when

the second is not, the first will not be either, but when the second is, there is no necessity for the first to be. But it is impossible for the same thing to be of necessity both when a certain thing is and when that same thing is not (I mean, for example, for B to be of necessity large if A is white, and for B to be of necessity large if A is not white). For whenever it is the case that if this thing (A) is white, that thing (B) is necessarily large, and that if B is large C is not white, if A is white, it is necessary that C is not white. And when there are two things such that if one of them is, it is necessary for the other to be, if the latter is not, the first necessarily is not. So if B is not large, A cannot be white. But if it is necessary for B to be large when A is not white, it results of necessity that when B is not large, this very thing (B) is large. But that is impossible: for if B is not large, A will of necessity not be white; therefore, if B will also be large when A is not white, it follows that if B is not large it is large, as it would through three terms.

2.5
Circular or Reciprocal Proof: First Figure

Proving in a circle or reciprocally is taking the conclusion and one of the premises (taken in reversed order of predication) and concluding through them the remaining premise that was assumed in the other deduction. For example: supposing someone who was required to prove that A belongs to every C and proved this through B, if he next were to prove that A belongs to B by supposing A to belong to C and C to B (previously, he supposed B to belong to C, in the reverse order). Or, if it is required to prove that[96] B belongs to C, if he supposes A to be predicated of C (which was the conclusion) and B predicated of A (previously, A was supposed as predicated of B, in the reverse order). Proving reciprocally is not possible otherwise. For if another middle is taken, it will not be in a circle, for neither of the same premises is taken. And if one of these premises is taken, it is necessary that it be only one. For if both are taken, the conclusion will be the same, but it must be different.

In the case of terms that do not convert with each other, then, the deduction comes about from one undemonstrated premise (for it cannot be demonstrated through these terms that the third term belongs to the middle or the middle to the first). But with terms that do convert, they can all be proved through each other—for example, if A, B, and C convert with each other. For let conclusion AC have been proved through middle B, and again AB through the conclusion together with premise BC converted, and likewise BC through the conclusion and premise AB converted. Both premise CB and premise BA then need to be demonstrated; for we have used only these premises as undemonstrated. Therefore, if B is taken to

96. Retaining ὅτι.

belong to every C and C to every A, there will be a deduction relating B to A. Next, if C is taken to belong to every A and A to every B, it is necessary for C to belong to every B. In both of these deductions, premise CA was taken as undemonstrated (for the others had been proved). Consequently, if we can demonstrate this premise, all of the premises will have been proved through each other. Accordingly, if C is supposed to belong to every B and B to every A, both the premises taken have been demonstrated, and it is also necessary for C to belong to A. It is evident, then, that only with terms that convert can there be circular or reciprocal demonstrations: for others, it is as we said previously.[97] It also happens that even in these cases we use the very thing proved for its demonstration. For "C is said of B" and "B is said of A" are proved by means of taking "C is said of A," but "C is said of A" is proved through these [first two] premises; consequently, we use the conclusion for its demonstration.

In the case of privative deductions, reciprocal proof is as follows. Let B belong to every C and A to no B (the conclusion is that A belongs to no C). If one must next conclude that A belongs to no B (which one previously supposed), let A belong to no C and C to every B (for that way the premise is reversed). But if it is required to conclude that B belongs to C, AB can no longer be converted in the same way (for "B belongs to no A" and "A belongs to no B" are the same premise). Instead, one must take B to belong to all of what A belongs to none of. Let A belong to none of the Cs[98] (which was precisely the conclusion), and let B be taken to belong to all of what A belongs to none of. It is necessary, then, for B to belong to every C. Consequently, each of the three premises has become a conclusion; and this is what it is to demonstrate in a circle: to take the conclusion and one premise reversed and deduce the remaining premise.

In the particular deductions, the universal premise cannot be demonstrated through the others, but the particular premise can be. It is evident that it is not possible to demonstrate the universal premise. For a universal is proved by means of universals, but the conclusion is not universal, and one must prove from the conclusion and the other premise. Moreover, no conclusion comes about at all when the [other] premise is converted; for both premises become particular. The particular premise can be demonstrated, however. For let A have been proved of some C through B. Then, if B is taken to belong to every A and the conclusion remains, B will belong to some C (for it becomes the first figure, and A is the middle). But if the deduction is privative, the universal premise cannot be proved because of what was also stated previously. However, the particular premise can be, if AB is converted in the same way as in the case of the universal deductions (that is, that what A does not belong to some of, B belongs to some of). For otherwise, no deduction comes about because the particular premise is negative.

97. $57^{b}32–35$.
98. Reading μηδενὶ τῶν Γ.

2.6
Circular or Reciprocal Proof: Second Figure

In the second figure, the affirmative cannot be proved this way but the privative can be. The positive, then, cannot be proved because the premises are not both affirmative (for the conclusion is negative, and a positive was proved from premises that are both affirmative). But the negative is proved as follows. Let A belong to every B and to no C (the conclusion is that B belongs to no C). Then, if B is taken to belong to every A and to no C,[99] it is necessary for A to belong to no C. For it becomes the second figure, and the middle is B. And if AB was taken as privative and the other premise as positive, it will be the first figure. For C belongs to every A and B to no C, so that B does not belong to any A, nor, therefore, A to any B. A deduction does not come about through the conclusion and one premise, then, but there will be one when another premise is taken in addition.

If the deduction is not universal, the universal premise cannot be proved, due to the same cause that we also said previously. The particular premise, however, is proved when the universal is positive. For let A belong to every B and not to every C (the conclusion is BC). Therefore, if B is supposed to belong to every A and not to every C, A will not belong to some C (the middle is B). But if the universal premise is negative, premise AC cannot be proved by converting AB (for it results either that both the premises are negative or that one of them is, so that there will not be a deduction). However, it can be proved in a way similar to the case of the universal deductions if A is taken to belong to some of what B does not belong to some of.

2.7
Circular or Reciprocal Proof: Third Figure

In the third figure, when both the premises are supposed as universal it is not possible to prove reciprocally. For a universal is proved through universals, but the conclusion **59ᵃ1** in this figure is always particular, and so it is evident that it is not possible at all to prove the universal premise through this figure.

But if one premise is universal and one particular, sometimes it can be done and sometimes it cannot. When both premises are taken as affirmative, then, and the universal is with the minor extreme, it can be done; but when it is with the other extreme, it cannot be. For let A belong to every C and B belong to some C (the conclusion is AB). Therefore, if C is taken to belong to every A, it has been proved that C belongs to some B, but it has not been proved that B belongs to some C. And yet it is necessary that if C belongs to some B, B also belongs to some C. However, it is not the same thing for this to belong to that and for that to belong to this. Instead, it

99. Retaining τῷ δὲ Γ μηδενί.

must be supposed in addition that if this belongs to some of that, that also belongs to some of this. But when this premise has been taken, the deduction no longer comes about from the conclusion and the other premise. But if B belongs to every C and A to some C, premise AC can be proved if C is supposed to belong to every B and A to some B. For if C belongs to every B and A to some B, it is necessary for A to belong to some C (B is the middle). And when one premise is positive, the other premise is privative, and the positive premise is universal, the other premise can be proved. For let B belong to every C, and let A not belong to some C (the conclusion is that A does not belong to some B). Then, if it is supposed in addition that C belongs to every B, it is necessary for A not to belong to some C (B is the middle). But when the privative premise is universal, the other premise cannot be proved, unless, as in the previous cases, it is supposed that this term belongs to some of what the other does not belong to some of—for example, if A belongs to no C and B belongs to some C (the conclusion is that A does not belong to some B). Therefore, if it is supposed that C belongs to some of what A does not belong to some of, it is necessary for C to belong to some B. Otherwise the other premise cannot be proved by converting the universal premise; for there will not be a deduction at all.

{It is evident, then, that in the first figure, reciprocal proof comes about both through the third figure and through the first. For when the conclusion is positive, the proof is through the first figure, but when the conclusion is privative it is through the last (for it is taken that what this belongs to none of, the other belongs to all of). And in the middle figure, when the deduction is universal, reciprocal proof is both through the same figure and through the first; but when the deduction is particular, it is through both the same and the last. And in the third figure, all reciprocal proofs are through the same figure. It is also evident that in the third and the middle figures, the deductions which do not come about through the same figure are either not in accord with circular proof or are incomplete.}[100]

2.8
Converting Deductions: First Figure

To convert is to make a deduction either that the [first] extreme does not belong to the middle term, or that the middle term does not belong to the last extreme, by reversing the conclusion. For if the conclusion is converted and one premise remains, it is necessary for the remaining premise to be done away with (for if that premise is so, the conclusion will be as well). But it makes a difference whether we convert the conclusion oppositely or contrarily; for the same deduction does not come about when it is converted in each way (but this will be clear through what follows). I say that "to every" is the opposite of "not to every," and "to some" is the opposite of "to

100. Secluded as probably inauthentic.

none," and I say that belonging "to every" converts contrarily with "to none," and "to some" with "not to some."

For let A have been proved of C through middle term B. If A is supposed to belong to no C and to every B, B will belong to no C. And if A is supposed to belong to no C and B to belong to every C, A will not belong to every B (but not simply to none; for a universal was not proved through the last figure). In general, the premise with the major extreme cannot be disestablished universally through conversion; for it is always done away with through the third figure. For it is necessary to take both the premises as relating to the last extreme term. And likewise if the deduction is privative. For let it have been proved through B that A belongs to none of the Cs.[101] Then, if A is supposed to belong to every C and to no B, B will belong to none of the Cs.[102] And if A and B are taken to belong to every C, A will belong to some B (but it belonged to none).

But if the conclusion is converted oppositely, the deductions will also be opposite, not universal (for one premise always becomes particular, so that the conclusion will also be particular). For let the deduction be positive, and let it be converted in this way. Then, if A does not belong to every C but belongs to every B, B will not belong to every C; and if A does not belong to every C but B does, A will not belong to every B. And similarly if the deduction is privative. For if A belongs to some C and to no B, B will not belong to some C (not simply to none); and if A belongs to some C and B to every C (which was taken originally), A will belong to some B.

In the case of the particular deductions, when the conclusion is converted oppositely both premises are done away with; but when it is converted contrarily, neither premise is (for doing away with it through conversion (with the conclusion falling short) [of a universal] no longer follows, as it did in the case of universal deductions, but instead it does not follow that anything is done away with at all). For let A have been proved of some C. Then if A is supposed to belong to no C and B to some, A will not belong to some B; and if A is supposed to belong to no C and to every B, B will belong to no C. Consequently, the premises are both done away with. But if it is converted contrarily, neither premise is done away with. For if A does not belong to some C and belongs to every B, B will not belong to some C, but the initial thing has still not been done away with (for it is possible to belong to some and not to belong to some). But no deduction of AB, the universal premise, comes about at all. For if A does not belong to some one of the[103] Cs and B does belong to some one of the Cs, neither of the premises is universal. And similarly if the deduction is privative. For if A is taken to belong to every C, the premises are both done away with, while if it is taken to belong to some, neither premise is (the demonstration is the same).

101. Reading τῶν Γ
102. Reading τῶν Γ.
103. Reading τῶν Γ.

2.9
Converting Deductions: Second Figure

In the second figure, the premise with the major extreme cannot be done away with contrarily, regardless of which sort of conversion we use. For the conclusion will always be in the third figure, and there was no universal deduction in that. However, we can do away with the other premise similarly by conversion. (By "similarly," I mean contrarily if the conclusion is converted contrarily and oppositely if it is converted oppositely.) For let A belong to every B and to no C (the conclusion is BC). Therefore, if B is taken to belong to every C and premise AB remains, A will belong to every C. For it becomes the first figure. And if B is taken to belong to every C and A to no C, A will not belong to every B (the figure is the last). But if BC is converted oppositely, premise AB can be proved similarly and premise AC oppositely. For if B is supposed to belong to some C and A to no C, A will not belong to some B. Next, if B belongs to some C and A to every B, then A belongs to some C (so that the opposite deduction results). And it can be proved similarly if the premises are in the reverse relation.

But if the deduction is particular, when the conclusion is converted contrarily neither of the premises is done away with (as they also were not in the first figure), but when the conclusion is converted oppositely, both premises are. For let A be put as belonging to no B and to some C (the conclusion is BC). Then if B is put as belonging to some C and premise AB remains, the conclusion will be that A does not belong to some C, but the initial thing has not been done away with (for it is possible to belong to some and not belong to some). Next, if B is supposed to belong to some C and A to some C, there will not be a deduction (for neither of the premises taken is universal), so that AB is not done away with. However, if it is converted oppositely, **$60^{b}1$** both premises are done away with. For if B is taken to belong to every C and A to belong to no B, A will belong to no C (but it belonged to some). Next, if B belongs to every C and A to some C, A will belong to some B. There is the same demonstration if the universal premise is positive.

2.10
Converting Deductions: Third Figure

In the third figure, when the conclusion is converted contrarily, neither of the premises is done away with in any of the deductions; but when it is converted oppositely, both premises are done away with, and in all of the deductions. For let A have been proved to belong to some B, let C be taken as middle term, and let the premises be universal. Then, if A is supposed not to belong to some B and B to belong to every C, no deduction of A and C comes about. Nor will there be a deduction of B and C if A does not belong to some B and belongs to every C.

And it can be proved similarly if the premises are not universal. For either it is necessary for both premises to be particular because of the conversion, or the universal is with the minor extreme, and there was no deduction in this way in either the first figure or the middle. But if it is converted oppositely, both premises are done away with. For if A belongs to no B and B to every C, then A will belong to no C. Next, if A belongs to no B and to every C, then B will belong to no C. And likewise if one premise is not universal. For if A belongs to no B and B to some C, A will not belong to some C; and if A belongs to no B and to every C, then B will belong to no C.

And similarly if the deduction is privative. For let A have been proved not to belong to some B, and let BC be positive and AC negative (for this is the way a deduction came about). Then, when the contrary of the conclusion is supposed, there will not be a deduction. For there was no deduction of A and C if A belonged to some B and B to every C, there was no deduction of A and C. Nor was there a deduction of B and C if A to some B and to no C. Consequently, the premises are not done away with. But when the opposite is, they are done away with. For if A to every B and B to every C, then A to every C: but it belonged to none. Next, if A to every B and to no C, then B to no C (but it belonged to every C). And it is proved similarly if the premises are not universal. For AC becomes both universal and privative, while the other [premise] is particular and positive. Therefore, if A to every B and B to some C, A to some C follows (but it belonged to none). Next, if A to every B and to no C, then B to no C (but it was supposed that it belongs to some). If A to some B and B to some C, no deduction comes about. Nor if A is taken to belong to some B and to no C either. So, the premises are done away with in the former way but not in the latter.

It is therefore evident through what has been said how a deduction comes about in each of the figures when the conclusion is converted, and when it is contrary to the premise and when opposite; also, that in the first figure the deductions come about through the middle figure and the last, and that the premise with the minor extreme is always done away with through the middle figure and the premise related to the major extreme rejected through the last figure; that in the second figure, the deductions come about through the first and the last figures; that the premise with the minor extreme is always done away with through the first figure and the premise with the major extreme through the last; that in the third figure, the deductions come about through the first and the middle figures, and the premise with the major extreme is always done away with through the first figure and the premise with the minor extreme through the middle figure. It is evident, then, what converting is, and how it is possible in each figure, and what deduction comes about.

2.11
Deduction through the Impossible: First Figure

A deduction through the impossible is proved when the contradictory of the conclusion is put [as a premise] and one of the premises [of the deduction] is taken in addition. This comes about in all the figures; for it is like conversion but differs in that it is converting when a deduction has already come about and both the premises have been taken, while it is reduction to the impossible not when the opposite has previously been agreed to but when it is obvious that it is true. The terms are similarly related in both, and the way of taking premises is the same for both. For example, if A belongs to every B and C is the middle, if A is assumed to belong either not to every B, or to none, and to belong to every C (which was [assumed as] true), it is necessary that C belongs either to no B or not to every B. But this is impossible; consequently, what was assumed is false. Therefore, its opposite is true. And similarly in the other figures. For whatever deductions admit of conversion also admit of deduction through the impossible.

The other problems, then, are all proved through the impossible in all the figures, but a universal positive conclusion is proved in the middle and the third figures but not proved in the first. For let A be assumed not to belong to every B, or to belong to none, and let the other premise be taken in addition from one side or the other, either that C belongs to every A or that B belongs to every D (for in that way it will be the first figure). Then if A is assumed not to belong to every B, a deduction does not come about, no matter which side the premise is taken from, but if A is assumed to **61^b1** belong to no B, when premise BD is supposed in addition there will be a deduction of a falsehood, but what was proposed is not proved. For if A belongs to no B and B to every D, A will belong to no D. But let this be impossible: it is then false that A belongs to no B. But it is not the case that if "to none" is false then "to every" is true. And if a premise CA is supposed in addition, a deduction does not come about, nor when A is assumed not to belong to every B. It is therefore evident that "belongs to every" is not proved through the impossible in the first figure.

But "belongs to some" and "belongs to none" and "does not belong to every" are proved. For let A be assumed to belong to no B, and let B be supposed to belong to every or to some C. Then it is necessary that A belongs to no C or not to every C. But this is impossible—for let it be true and evident that A belongs to every C—so that if this is false, it is necessary that A belongs to some B. However, if the other premise is taken as attached to A, there will not be a deduction, nor will there be one when the contrary of the conclusion—that is, that A does not belong to some B—is assumed. It is evident, then, that it is the opposite [of the conclusion] that must be assumed.

Next, let A be assumed to belong to some B, and let C be supposed to belong to every A. It is then necessary for C to belong to some B. But let this be impossible, so that what was assumed is false. In that case, that it belongs to none is true. And similarly if CA is supposed as privative. But if the premise attached to B was supposed,

there will not be a deduction. And if the contrary should be assumed, there will be a deduction and something impossible will result, but what was proposed is not proved. For let A be assumed to belong to every B, and let C be supposed to belong to every A. Then, it is necessary that C belongs to every B. But this is impossible; consequently, it is false that A belongs to every B. However, if it does not belong to every, it is still not necessary that it belongs to none. And similarly if the other premise is taken as attached to B. For there will be a deduction and something impossible, but the hypothesis is not done away with. Consequently, it is the opposite that must be assumed.

In order to prove that A does not belong to every B, it must be assumed that it belongs to every. For if A belongs to every B and C to every A, C will belong to every B, so that if this is impossible, what was assumed is false. And similarly if the other premise was supposed as attached to B. Likewise if CA was privative, for a deduction also comes about in this way. However, if the privative premise is attached to B, nothing is proved. And if A was assumed to belong to some rather than to every B, it is not proved that it does not belong to every, but rather that it belongs to none. For if A is taken to belong to some B and C to belong to every A, C will belong to some B. So if this is impossible, it is false that A belongs to some B, so that it is true that it belongs to none. But if this is proved, then something true is also done away with (for A belonged to some B and did not belong to some). In addition, neither does the impossibility follow depending on the hypothesis.[104] For the hypothesis would then be false, since it is impossible to deduce something false from true premises, while in fact it is true (for A belongs to some B). Consequently, it must be assumed, not that it belongs to some, but that it belongs to every. And similarly if we want to prove that A does not belong to some B. For if not to belong to some and not to belong to every are the same, there will be the same demonstration for them both.

It is evident, then, that it is not the contrary but rather the opposite that must be assumed in all these deductions. For in this way there will be a necessary result, and what is claimed will be accepted. For if either the affirmation or the negation is true of everything, when it is proved that the negation is not true, it is necessary for the affirmation to be true. Moreover, if someone does not suppose the affirmation to be true, it is acceptable to claim the negation. To claim the contrary, however, is not appropriate either way. For neither is it necessary for "belongs to every" to be true if "belongs to none" is false, nor is it acceptable that if the one is false then the other is true.

2.12
Deduction through the Impossible: Second Figure

It is evident, then, that in the first figure all the other problems are proved through the impossible but the universal positive is not so proved. But in the middle and the

104. Reading οὐ παρὰ τὴν ὑπόθεσιν συμβαίνει τὸ ἀδύνατον.

last figures, this problem is proved as well. For let A be assumed not to belong to every B, and let A be supposed to belong to every C. So then, if A does not belong to every B and belongs to every C, then C will not belong to every B. But this is impossible—for let it be evident that C belongs to every B—so that the assumption is false. Therefore, it is true that A belongs to every B. But if the contrary is assumed, there will be a deduction and an impossibility, but yet what was proposed is not proved. For if A belongs to no B and to every C, then C will belong to no B. But this is impossible, so that it is false that it belongs to none. However, it is not the case that if that is false, it is true that C belongs to every B.

To prove that A belongs to some B, let A be assumed to belong to no B, and let it belong to every C. Then it is necessary for C to belong to no B. Consequently, if this is impossible, it is necessary that A belongs to some B. And if it is assumed not to belong to some B, the results will be the same as in the first figure.

Next, let A be assumed to belong to some B, and let it belong to no C. It is then necessary that C does not belong to some B. But it belonged to every one, so that what was assumed is false. Therefore, A will belong to no B.

To prove that A does not belong to every B, let it be assumed to belong to every B and to no C. It is then necessary for C to belong to no B. But this is impossible; consequently, that A does not belong to every B is true. It is evident, then, that all the deductions can come about through the middle figure. **$62^{b}1$**

2.13
Deduction through the Impossible: Third Figure

And similarly through the last figure. For let A be taken not to belong to some B and to belong to every C. Therefore, A does not belong to some C. If this is impossible, it is false that A does not belong to some B, and consequently true that it belongs to every B. But if A is assumed to belong to no B, although there will be a deduction and something impossible will follow, what was proposed is not proved (for if the contrary is assumed, the results are the same as in the previous cases). Instead, this hypothesis must be chosen for proving that A belongs to some B. For if A belongs to no B and C to some B, then A will not belong to every C. Therefore, if this is false, it is true that A belongs to some B.

And to prove that A belongs to no B, let it be assumed that it belongs to some, and let C be supposed as belonging to every B. Then it is necessary for A to belong to some C. But it belonged to none; consequently, it is false that A belongs to some B. However, if A is assumed to belong to every B, what was proposed is not proved. That hypothesis must be taken instead for proving that A does not belong to every B. For if A belongs to every B and C to every B, then A belongs to some C. But this was assumed not to be so; consequently, it is false that it belongs to every B. And if this is so, it is true that it does not belong to every B. If it is assumed to belong to some, the results will be the same as what was said previously.

It is evident, then, that in all deductions through the impossible it is the opposite that must be assumed. It is also clear that an affirmative is, in a way, proved in the middle figure and a universal in the last.

2.14
Comparison of Probative and Through-the-impossible Demonstration

Demonstration to the impossible differs from probative demonstration in that it puts as a premise what it intends to do away with by reducing to an agreed falsehood, while a probative demonstration begins from agreed suppositions. More precisely, both demonstrations take two agreed premises, but one takes the premises that the deduction is from while the other takes one of these premises and, as the other premise, the contradictory of the conclusion. Also, in the former case it is not necessary for the conclusion to be known or even supposed in advance to be so or not, while in the latter case it is necessary to assume in advance that it is not so. It makes no difference whether the conclusion is an affirmation or a negation, but rather it is similar concerning both sorts of conclusion.

Everything concluded probatively can also be proved through the impossible, and everything proved through the impossible can be concluded probatively, through the same terms. For when the deduction comes about in the first figure, the true
63ᵃ1 conclusion will be in the middle figure or the last (a privative conclusion in the middle figure and a positive conclusion in the last). When the deduction is in the middle figure, the true conclusion is in the first figure for all the problems. When the deduction is in the last figure, the true conclusion will be in the first or the middle figure (affirmative conclusions in the first figure and privatives in the middle). For let A have been proved of no B, or not of every B, through the first figure. The hypothesis, then, was that A belongs to some B, and C was supposed to belong to every A and to no B (for that is how the deduction and the impossibility came about). But this is the middle figure: "if C belongs to every A and to no B"; and it is evident from these premises that A belongs to no B. And similarly if it has been proved that it does not belong to every B. For the hypothesis is that it belongs to every B, and C was supposed to belong to every A and not to every B. Likewise if CA is supposed as privative (for the middle figure comes about that way as well). Next, let A have been proved as belonging to some B. The hypothesis, then, is that it belongs to none, and B was taken to belong to every C and A to belong either to every or to some C (for in this way there will be an impossibility). But this is the last figure: "if A and B to every C"; and it is evident from these premises that it is necessary for A to belong to some B. Similarly if either B or A is supposed to belong to some C.

Next, in the middle figure, let A have been proved to belong to every B. The hypothesis then was that A does not belong to every B, and A was supposed to belong to every C and C to every B (for this is how there will be an impossibility). But this is

the first figure: "A to every C and C to every B." And similarly if A has been proved to belong to some B. For the hypothesis was that A belongs to no B, and A was supposed to belong to every C and C to some B. If the deduction is privative, the hypothesis is that A belongs to some B, and A is supposed to belong to no C and C to every B, so that it becomes the first figure. Likewise if the deduction is not universal and A has instead been proved not to belong to some B. For the assumption was that A belongs to every B, and A was supposed to belong to no C and C to some B (for in this way it is the first figure).

Next, in the third figure, let A have been proved to belong to every B. The hypothesis, therefore, was that A does not belong to every B, and C was supposed to belong to every B and A to every C (for that is how there will be an impossibility). But this **$63^{b}1$** is the first figure. And likewise if the demonstration is particular. For the hypothesis was that A belongs to no B, and C was supposed to belong to some B and A to every C. If the deduction is privative, the hypothesis was that A belongs to some B, and C was supposed to belong to no A and to every B (but this is the middle figure). And similarly if the demonstration is not universal. For the hypothesis will be that A belongs to every B, and C was supposed to belong to no A and to some B (but this is the middle figure).

It is evident, then, that each problem can also be proved probatively through the same terms. Similarly, when deductions are probative, it will also be possible to reduce them to the impossible using the terms taken when the premise opposite to the conclusion is supposed. For the same deductions come about as through conversion; consequently, we also know at once the figure through which each one will be possible. It is clear, then, that every problem can be proved in both ways, through the impossible as well as probatively, and that it is not possible to separate one of them off.

2.15
Deductions from Opposite Premises

In which figures it is possible to deduce from opposite premises, and in which figures it is not, will be evident in what follows.

I say that verbally there are four [pairs of] opposite premises: "to every" and "to no," "to every" and "not to every," "to some" and "to no," and "to some" and "not to some." In truth, however, there are three, for "to some" and "not to some" are only opposites verbally. Among these, I call the universal premises "contraries" ("to every" is contrary to "to none," as, for example, "every science is excellent" is contrary to "no science is excellent"), and the other pairs of premises "opposites."

In the first figure, then, there cannot be a deduction from opposite premises, whether affirmative or negative. There cannot be an affirmative deduction because both premises must be affirmative, whereas opposite premises are an affirmation and

negation. There cannot be a privative deduction, on the other hand, because opposite premises predicate and deny the same thing of the same thing, but the middle term in the first figure is not said of both extremes; rather, one is denied of it and it is predicated of the other, and such premises are not opposed.

But in the middle figure, it is possible for a deduction to come about both from opposite and from contrary premises. For let A stand for good and B and C for **64ᵃ1** science. If someone supposed every science to be good[105] and also no science to be good—A belongs to every B and to no C—so that B belongs to no C: no science, therefore, is a science. Similarly if, supposing every science to be excellent he supposed medicine not to be excellent. For A belongs to every B and to no C, so that a particular science will not be a science. And if A to every C and to no B, and B is science, C medical science, and A supposition. For while supposing no science to be supposition, he has supposed some science to be supposition. This differs from the previous case because of the conversion of the terms: previously, the affirmative was with B, but now it is with C. And likewise if one premise or the other is not universal. For the middle will always be what is said negatively of one extreme and affirmatively of the other. Consequently, it is possible for opposites to give a conclusion; not always or in all ways, however, but if the terms below the middle are so related that they are either the same or as a whole to a part. Otherwise, it is impossible, for the premises will be neither contraries nor opposites at all.

In the third figure, there can never be an affirmative deduction from opposite premises due to the cause also stated in application to the first figure, but there can be a negative deduction both when the terms are universal and when they are not universal. For let B and C stand for science and A for medicine. Therefore, if someone takes all medicine to be a science and no medicine to be a science, he has supposed B to belong to every A and to no C, so that some science will not be a science. And similarly if premise BA is supposed as not universal. For if some medicine is a science and next no medicine is a science, it follows that some science is not a science. When the terms are supposed as universal, the premises are contrary, but when one or the other term is particular, the premises are opposites.

We should notice here that although it is possible to assume opposites this way (as we said every science is good and then said no science is good, or that some science is not), this ordinarily does not escape our notice. But it is also possible to deduce one or the other of them through different questions or to obtain it as was said in the *Topics*.[106]

Since there are three oppositions of affirmations, it follows that opposites can be supposed in six ways: "to every" and "to no," or "to every" and "not to every," or "to some" and "to no," and next converting this with respect to the terms (for **64ᵇ1** example, supposing A to belong to every B and to no C, or to every C and to no B; or

105. In this argument Aristotle unusually uses two different, but often synonymous, words (*agathos* and *spoudaios*) for term A.
106. 163ᵃ14–28.

supposing it to belong to all of one and not to all of the other, and again converting this with respect to the terms). And similarly in the third figure. Consequently, it is evident both in how many ways and in which figures it is possible for a deduction through opposite premises to come about.

It is also evident that while it is possible to deduce a true conclusion from falsehoods (as was said previously[107]), it is not possible to do so from opposite premises. For the [conclusion of the] deduction will always be contrary to the subject matter—as not being good, if it is good, or not being an animal, if it is animal—because the deduction is from a contradiction, and the subject terms are either the same or one is a whole and the other a part. And it is clear that in fallacies nothing prevents the contradictory of the hypothesis from coming about—for example, that it is not odd if it is odd. For from opposite premises, a contrary was deduced; so, if such premises are supposed, the contradictory of the hypothesis will follow.

But we must take note that it is not possible to conclude contraries from a single deduction in this way so as to get as the conclusion that what is good is not good, or something else of this sort, unless the premise of this sort is taken directly—for example, "every animal is white and not white, and a human is an animal." Instead, either one must also take the contradictory (that is, that every science is supposition), and next take as premises that medicine is a science and that no medicine is supposition, in the way that refutations happen—or else get the contradiction from two deductions. But to take them so that the things supposed are in truth contraries is not possible in any other way than this, as was said previously.

2.16
Asking for the Initial Thing

Asking for or assuming the initial thing is, to put it in a kind, a matter of not demonstrating what was proposed. But that happens in many ways: if one entirely fails to deduce, or if one does deduce but through [premises] more unknowable [than what was proposed] or equally unknowable [as it is], or if one deduces what is prior through what is posterior (for a demonstration is through what is both more persuasive and prior). None of these, then, is asking for the initial thing. However, given that some things are of such a nature as to be known through themselves and some are of such a nature as to be known through others—that is, the starting-points are known through themselves and those below the starting-points are known through other things—therefore, whenever someone tries to prove through itself what is not knowable through itself, he is asking for the initial thing.

This can be done in such a way as to claim directly what was proposed, but it is also possible to do it by transferring the argument over to other premises that are of such

107. 2.2–4.

a nature as to be proved through the initial thing and demonstrating the initial thing through them—for example, if A is proved through B and B through C, but C is of such a nature as to be proved through A; for the result is that those who deduce in this way prove A through itself. This is precisely what those who think they construct proofs that there are parallels do; for they do not notice that they themselves suppose premises that it is not possible to demonstrate if there are no parallels. Thus, it follows for those who deduce in this way that they are saying a given thing is so if it is so. But in that way everything would be knowable through itself, which is impossible.

So then, if someone should ask for the premise that A belongs to B when it is not clear that A belongs to C and equally unclear that it belongs to B, although it is not yet clear whether he is asking for the initial thing, he is clearly not demonstrating (for what is equally unclear is not the starting-point of a demonstration). However, if B is so related to C as to be the same, or if it is clear that they convert or that one belongs[108] to the other, he is asking for the initial thing. For he could also prove that A belongs to B through those terms, if he converted it (this is what actually prevents him, not the way it is proved). But if he did this, he would do what was said and convert the three of them. And likewise, if he were to suppose that B belongs to C, though that was as unclear as that A did, he would not yet be asking for the initial thing, but he is not demonstrating. However, if A is the same as B because A either converts with it or follows it, then he is asking for the initial thing, due to the same cause. For it was said what "asking for the initial thing" means for us: it is proving through itself what is not clear through itself.

Therefore, if asking for the initial thing is proving through itself what is not clear through itself—which is to say, not proving—then if what is being proved and what someone is proving it through are equally unclear, either because the same things belong to the same thing or because the same thing belongs to the same things, it will be possible to ask for the initial thing both ways in the middle figure and in the third, and in a positive deduction in both the third figure and the first. When the conclusion is deduced negatively, it is possible when the same things are denied of the same, though not possible for both the premises similarly, because the terms do not convert with respect to negative deductions (and likewise in the middle figure). In demonstrations, it is asking for the initial thing when the premises are so related in truth, but in dialectical arguments when they are so related in accord with belief.

2.17
"Falsehood Not Because of This"

"The falsehood does not follow depending on this"—something we often have occasion to say in arguments—is, to begin with, something that occurs in connection with deductions to the impossible, where it is said in relation to the contradiction of

108. Reading ὑπάρχει.

what was proved by reduction to the impossible. For unless the argument had come to a contradiction, no one would say "not depending on this," but rather that something false was put among the previous suppositions. Nor will anyone say it of a probative demonstration, for that does not suppose what it contradicts. Moreover, when something is done away with probatively through ABC, it cannot be said that the deduction has not come about because of what was supposed. For we say "it does not come about depending on this" when, although "this" is done away with, the deduction nonetheless comes to a conclusion, and that is precisely what is not possible in probative deductions (for when the hypothesis has been done away with, the deduction related to it will no longer exist). It is evident, then, that "not depending on this" is said in deductions to the impossible and when the initial hypothesis is so related to the impossibility that, whether this hypothesis is or is not made, the impossibility nonetheless follows. **65b1**

The most obvious way for the false conclusion not to be dependent on the supposition, then, is when the deduction from the middle terms to the impossibility is unconnected with the hypothesis (which was also said in the *Topics*).[109] For this is what putting a non-cause as the cause is. For example, if someone intending to prove that the diagonal is incommensurable makes use of Zeno's argument that it is not possible to move and leads the argument to this impossibility. For the falsehood is not connected in any way at all to the initial assertion.

Another way is if the impossibility is connected to the hypothesis but nonetheless does not follow through it. For it is possible for this to happen when taking something connected either upward or downward. For example, if A is put as belonging to B, B to C, and C to D, and this statement, "B belongs to D," is false. For if B nonetheless belongs to C, and C to D, when A is taken away, the falsehood would not be through the initial hypothesis. Or next, if someone takes something connected upward, for example, taking A to belong to B, E to A, and F to E, and it is false that F belongs to A. For in this way as well, the impossibility will nonetheless result if the initial hypothesis is done away with.

The impossibility must instead be connected to the initial terms. For this is the way it will be through the hypothesis: in the downward direction, taking something connected to the term that is predicated (for if it is impossible for A to belong to D, then, when A is taken away there will no longer be a falsehood); or in the upward direction, taking something connected to that term of which the other is predicated (for if it is not possible for F to belong to B, then when B is taken away the impossibility will no longer result). And similarly also when the deductions are privative.

It is evident, then, that when the impossibility is not related to the initial terms, the falsehood does not follow depending on the assumption. Or rather, even in this way, might the falsehood not always result through the hypothesis? For if A was put as belonging, not to B, but to K, and K to C, and this to D, in this way also **66a1**

109. *SE* 167^b21–36 (Aristotle always cites *SE* as part of *Top.*).

the impossibility remains (and similarly also when taking the terms upward); consequently, since the impossibility results both when this is so and when it is not, it would not be dependent on the assumption. Or should we take "when this is not so the falsehood comes about nonetheless" not in this sense, that when something *else* is supposed the impossibility follows, but rather that when this is taken away the *same* impossibility is concluded through the remaining premises? For it is really not absurd for the same falsehood to result through several hypotheses, as, for example, it results that parallels intersect both if the internal angle is greater than the external and if a triangle has more than two right angles.

2.18
The Cause of a False Conclusion

A false argument happens because of its first falsehood. For every deduction is either from two premises or from more. If it is from two premises, then, it is necessary for one of these (or both) to be false (for a false deduction, as we saw,[110] is not possible from true premises). But if it is from more premises (for example, if C is deduced through AB and these are deduced through DEFG), among these higher things one will be false and, depending on it, the argument will be as well (for A and B are concluded through them). Consequently, the conclusion—that is, the falsehood—follows depending on one of these.

2.19
Watch for the Repeated Term When Debating

In order to avoid being argued down in deducing, be on the lookout, whenever someone is asking for premises in an argument without conclusions, against the same term being conceded twice in the premises, since we know that a deduction does not come about without a middle, and the middle is what is said multiple times. The way we must watch out for the middle with each sort of conclusion is evident because we know what sort is proved in each figure. We will not overlook this because we know how we are defending the argument.

When we are attacking, we should ourselves try to get away with the very thing we are warning to guard against when in the answering role. This will be possible if, first, the conclusions are not deduced in advance and are not obvious when the necessary premises have been obtained; next, if one does not ask for premises close in order, but as far as possible immediate. For example, let it be required to conclude A of F (the middle terms are BCDE). So, we should ask whether A belongs to B; next,

110. 53[b]11–25.

not whether B belongs to C, but whether D belongs to E; next after that, whether B belongs to C, and so on for the rest. And if the deduction comes about through a single middle term, we should begin from the middle term; for in this way the answerer will be most likely not to notice. **$66^{b}1$**

2.20
When There Is, or Is Not, a Refutation

Since we know when a deduction comes about—that is, what relations the terms are in—it is also evident both when there will and when there will not be a refutation. For it is possible for there to be a refutation either when everything asked gets an affirmative response or when the answers are given alternately (that is, one negative and the next affirmative). For there was a deduction when the terms were related both in the latter way and in the former. Consequently, if what is supposed is contrary to the conclusion, there is necessarily a refutation (for a refutation is the deduction of a contradiction). But if nothing should get an affirmative response, it is impossible for there to be a refutation. For there was no deduction when all the terms were privative, so that there is not a refutation either (for if there is a refutation, necessarily there is a deduction, though when there is a deduction it is not necessary that there is a refutation). And likewise if nothing should be supposed to belong to something as a whole in the answer (for the definition of a refutation and of a deduction will be the same).

2.21
Being Misled by Inconsistent Suppositions

Sometimes it happens that, just as we are deceived by the arrangement of the terms, so also deception arises in what we think about them—for example, if it is possible for the same thing to belong primarily to several others but someone has forgotten about one of them and thinks the term belongs to none of it, while knowing that it belongs to another one. For let A belong to B and to C intrinsically, and these likewise to every D. If someone thinks that A belongs to every B and this to every D, but also that A belongs to no C and this to every D, he will have both knowledge and ignorance about the same thing in the same respect. Next, this is possible if someone should be deceived about terms from the same column. For example, if A belongs to B, this belongs to C, and C to D, but he thinks that A belongs to every B and next to no C (for he will at the same time both know that it belongs and think it does not). From these premises, then, could anything be expected to result except that he does not think that very thing which he knows? For in a way he knows that A belongs to C through B (that is, in the way we know the particular in virtue of the universal); consequently, what he knows in a way, he also claims not to think at all—which is impossible.

Concerning the case mentioned previously, if the middle term is not from the same column, it is not possible to think both the premises with respect to each of the middles (for example, to think that A belongs to every B and to no C and that these both belong to every D). For it follows that the first premise is supposed contrarily (either unconditionally or in part). For if he thinks that A belongs to everything B belongs to and knows that B belongs to D, he also knows that A belongs to D. So then next, if he thinks that A belongs to none of what C belongs to, he thinks that A does not belong to what B belongs to some of. But to think that something belongs to everything B belongs to and then in turn think it does not belong to something B belongs to is contrary, either unconditionally or in part.

It is not possible to believe in this way, then, but nothing prevents one from thinking one of the premises relative to each of the middle terms, or both premises relative to [only] one—for example, supposing that A belongs to every B and B to every D and A in turn to no C; for this sort of deception is similar to the way we are deceived about particular premises. For example, if A belongs to everything B belongs to and B to every C, A will belong to every C. Therefore, if someone knows that A belongs to everything B belongs to, he also knows that it belongs to C. But nothing prevents him from being ignorant that C exists—for example, if A is two right angles, B stands for triangle, and C stands for a perceptible triangle: someone could think that C does not exist while knowing that every triangle has two right angles, so that he will at the same time know and be ignorant of the same thing. For "knows of every triangle that it has angles equal to two right angles" does not have just one sense: one is in virtue of having universal scientific knowledge, but the other is in virtue of having the particular knowledge. Therefore, in this way—in virtue of the universal sort—he does know, of C, that it has two right angles, but he does not know it in virtue of the particular sort. Consequently, he will not possess contrary states of knowledge. The argument in the *Meno*[111] that learning is remembering is like this. For it never follows that we scientifically know the particular in advance, but instead that we get the scientific knowledge of the particulars at the same time through the induction, as if we were recognizing something. For there are some things which we know straightaway—for example, knowing that something is equal] to two right angles if we see that it is a triangle. And similarly in other cases.

By means of the universal scientific knowledge, then, we observe the particulars, but we do not know them in virtue of the scientific knowledge appropriate to them. It is therefore possible to be deceived about them, but not contrarily. Instead, it is possible to have the universal scientific knowledge but be deceived in virtue of[112] the particular sort. Therefore, it is the same in the cases mentioned previously; for deception concerning a middle term is not contrary to scientific knowledge in accord with a deduction, nor is supposition concerning either of the middles. But nothing prevents

111. Plato, *Meno* 80d5–8; also *APo*. 71ᵃ29–30.
112. Reading τῇ.

someone who knows both that A belongs to the whole of B and that this in turn belongs to C from thinking that A does not belong to C—for example, knowing that every female mule is infertile, and that this is a female mule, but thinking that this one is pregnant. For he does not scientifically know that A belongs to C if he does not have both of them in view together. Clearly, therefore, if he knows the one but does not know the other, he will have been deceived. This is precisely what the relation is of the knowledge of the universal sciences to the scientific knowledge of particulars. For we do not know any perceptible object once it is outside our perception, even if we do happen to have perceived it previously, unless it is in virtue of universal knowledge, that is, in virtue of possessing the scientific knowledge appropriate to it but not in virtue of activating it. For we are said "to know scientifically" in three ways: by means of universal scientific knowledge, by means of the scientific knowledge appropriate to something, or by means of our activating it, and we are said to be deceived, therefore, in just as many ways. Nothing then prevents one from both knowing and being deceived about the same thing, though not contrarily. And this is precisely what happens to the person who knows the premise in accord with one of the sorts of knowledge but has not previously reflected on it. For in thinking that the female mule is pregnant, he does not possess scientific knowledge in the sense of activating it, but at the same time his deception through that thought is not contrary to his scientific knowledge, for a deception contrary to universal knowledge is a deduction.

Someone who thinks that the being for good is the being for bad will think that the being for good is the same as the being for bad. For let A stand for the being for good, B stand for the being for bad, and C again stand for the being for good. Then, since he thinks that B and C are the same, he will think that C is B, and next that B likewise is A, so that he will also think C is A. For just as if it were true that B is predicated of what C is predicated of, and A is predicated of what B is predicated of, it would also be true that A is predicated of C, so also in the case of thinking. And similarly also in the case of being [the same as]: for if C and B are the same, as again are B and A, C would also be the same as A. Consequently, it will be the same also in the case of thinking. Is this then necessary, if someone grants the first thing? But perhaps this is false, that someone thinks the being for good is the being for bad, unless coincidentally (for it is possible to think this in many ways). This must be investigated better.

2.22
On the Conversion of Terms

When the extremes convert, it is necessary that the middle also converts with both of them. For if A is proved to belong to C through B, and if it converts—that is, C belongs to everything that A does—B also converts[113] with A, that is, B will belong

113. Reading ἀντιστρέφει here and in the next sentence.

to everything A belongs to through middle term C. And C converts with B through A as the middle term.

Likewise in the case of not belonging. For example, if B belongs to C and A does not belong to B, neither will A belong to C. But if B converts with A, C will also convert with A. For let B not belong to A: therefore, neither will C (for B belonged to every C). And if C converts with B, A will also convert with it (for whatever B is true of all of, C is also true of that). And if C converts with[114] A, B also converts[115] with it. For whatever B belongs to, C belongs to, but whatever A belongs to, C does not belong to. (This case alone begins from the conclusion, while the other cases do not, as in the case of a positive deduction.)

Next, if A and B convert, and C and D likewise, and it is necessary for either A or C to belong to everything, B and D will be so related that one or the other of them belongs to everything. For since B belongs to what A belongs to, and D belongs to what C belongs to, and either A or C belongs to everything but not both of them together, it is also evident that either B or D belongs to everything but not both of them together (for here two deductions are combined). Next, if either A or B and either C or D belong to everything, but they cannot both belong at the same time, if A and C convert, B and D also convert. For if B does not belong to something D belongs to, A clearly does belong to it; and if A belongs to it, C does too (for they convert). Consequently, C and D will belong to it together. But that is impossible. For example, if what is incapable of coming to be is incapable of passing away and what is incapable of passing away is incapable of coming to be, it is necessary that what comes to be is capable of passing away and that what is capable of passing away comes to be.[116]

But when A belongs to the whole of B and of C, and it is predicated of nothing else, and B also belongs to every C, it is necessary that A and B convert. For since A is said only of B and C, and B is predicated both of itself and of C, it is evident that B will also be said of all that A is said of except for A itself. Next, when A and B belong to the whole of C and C converts with B, it is necessary that A belongs to every B. For since A belongs to every C and C belongs to B (because they convert), A also belongs to every B.

When A and B are two opposites of which A is more choiceworthy than B, and D is likewise more choiceworthy than C, then if [the combination] AC is more choiceworthy than [the combination] BD, A is more choiceworthy than D. For A is as much to be pursued as B is to be avoided (for they are opposites), and C is similarly related to D (for these are also opposites). Therefore, if A is equally as choiceworthy as D, B is equally to be avoided as C (for each is similarly related to each, what is to be pursued to what is to be avoided). Consequently, the both of them (AC) would

114. Rejecting the addition of καὶ.
115. Reading ἀντιστρέφει.
116. The Bekker text of this paragraph is reorganized as indicated.

be equally so as BD. But since A is in fact more choiceworthy [than D], it cannot be equally to be avoided [as D]. For then, BD would also be equally choiceworthy [as AD]. And if D were more choiceworthy than A, B would be less to be avoided than C (for the lesser is opposed to the lesser). And the greater good and lesser bad is more choiceworthy than the lesser good and greater bad; therefore, the combination, BD, would be more choiceworthy than AC. But in fact it is not. Therefore, A is more choiceworthy than D, and thus C is less to be avoided than B.

So, if every lover would choose, when it comes to his beloved, for him to be of such a sort as to grant [sexual] favors (A) without granting them (which C stands for) than for him to grant favors (which D stands for) without being of such a sort as to grant them (which B stands for), it is clear that A (being of such a sort) is more choiceworthy than granting favors. To be loved, therefore, is more choiceworthy than sexual intercourse, when it comes to his beloved. Therefore, love is more for friendship than for sexual intercourse. But if it is most of all for this, that is its end. Therefore, sexual intercourse is either not the end at all or is so for the sake of being loved. The other appetites and crafts are also like this.

2.23
The Figures Apply in Rhetoric and Everywhere Else

It is evident, then, how terms are related with respect to conversions and with respect to being more choiceworthy or more to be avoided. But now we must explain that not only do dialectical and demonstrative deductions come about through the figures previously mentioned, but so also do rhetorical ones and, in a word, any means of persuasion whatever in accord with whatever methodical inquiry.

We come to be persuaded about anything either through deduction or from induction. Induction, then—that is, a deduction from induction—is deducing one extreme to belong to the middle through the other extreme. For example, if B is the middle for AC, proving A to belong to B through C (for this is how we produce inductions). For example, let A be long-lived, B stand for not having bile, and C stand for the long-lived particular, such as a human, a horse, or a mule. A belongs to the whole C (for everything bileless[117] is long-lived); but B (not having bile) belongs to every C. Then, if C converts with B and the middle term does not extend beyond the extreme, it is necessary for A to belong to B. For it was proved earlier[118] that if two terms belong to the same thing and the extreme converts with one of them, the other one of the predicates will also belong to the term that converts with it. (But one must understand C as composed of every one of the particulars; for induction is through them all.)

117. Reading ἄχολον.
118. $68^{a}16–25$.

This is the sort of deduction there is of a first—that is, immediate—premise: for the deduction of those things of which there is a middle term is through that middle term, but the deduction of those of which there is no middle term is through induction. And in a way, induction is the opposite of deduction. For deduction proves the first extreme to belong to the third term through the middle, whereas induction proves the first extreme to belong to the middle through the third. By nature, therefore, the deduction through the middle term is prior and better known, but the deduction through induction is more obvious to us.

2.24
Paradigms

It is a paradigm when the [first] extreme is proved to belong to the middle through something that is like the third term. It must be known both that the middle belongs to the third and that the first belongs to what is like the third. For example, let A be bad, B undertaking war against neighbors, C stand for Athenians against Thebans, D stand for Thebans against Phocians. So then if we want to prove that warring with the Thebans is bad, it should be assumed that warring against one's neighbors is bad. (Conviction about this comes from similar cases, for example, that the war against the Phocians was bad for the Thebans.) Then, since [war] against one's neighbors is bad, and against the Thebans is against neighbors, it is evident that warring against the Thebans is bad. That B belongs to C and to D, then, is evident (for both are undertaking war against one's neighbors), as also is the premise that A belongs to D (for the war against the Phocians did not go to the advantage of the Thebans). But that A belongs to B will be proved through D. It would be the same way if proof of the middle about the extreme should come about through several terms.

It is evident, then, that a paradigm is neither as part to whole nor as whole to part, but rather as part to part, when both are below the same thing but one of them is known. It differs from induction because induction proves the extreme to belong to the middle from all the particulars and does not connect the deduction to the extreme, while a paradigm both does connect it and does not prove from them all.

2.25
Abduction

It is abduction when it is clear that the first term belongs to the middle but unclear that the middle belongs to the third, though nonetheless equally as convincing as the conclusion, or more so. Or also if there are few middles between the last term and the middle. For in all these ways it results that we are closer to scientific knowledge. For example, let A be teachable, B stand for scientific knowledge, and C justice.

Then it is evident that scientific knowledge is teachable but unclear whether virtue is scientific knowledge. Therefore, if BC is equally convincing as AC, or more so, it is abduction; for it is closer to knowing scientifically because of supposing something in addition that we previously did not have: the scientific knowledge of AC[119]). Or next, it is abduction if the middle terms between B and C are few; for in this way as well it is closer to knowing. For example, if D is squaring, E stands for rectilinear figure, F stands for circle. If there is only one middle term of E and F—that is, for a rectilinear figure together with lunes to become equal to a circle[120]—it would be closer to knowing. But when BC is not more convincing than AC and the middles are not few either, I do not call it abduction. Nor when BC is immediate: for that is scientific knowledge.

2.26
Objections

An objection is a premise contrary to a premise. It differs from a premise in that an objection can be particular while a premise either cannot be so at all or cannot be so in universal deductions. An objection is brought in two ways and through two figures: in two ways, because every objection is either universal or particular, and from two figures, because they are brought as premises opposite to a premise, and opposites are concluded only in the first and third figures. For when someone claims that it belongs to every, we object either that it belongs to none or that it does not belong to some; of these, "to none" is from the first figure and "not to some" from the last. **69^b1**

For example, let A stand for there being one scientific knowledge and B stand for contraries. When someone proposes that there is a single scientific knowledge of contraries, it is objected either that in general there is not the same scientific knowledge of opposites and contraries are opposites (so that the first figure comes about), or it is objected that there is not a single scientific knowledge of the known and the unknown (and this is the third figure: for of C, known and unknown, "being contraries" is true but "there being a single scientific knowledge of them" is false). Next, it is the same way with a privative premise. For if someone claims that there is not a single scientific knowledge of contraries, we say that there is the same scientific knowledge either of all opposites, or of some contraries (for example, of healthy and ill): "of every," then, is from the first figure, and "of some" from the third.

For unconditionally, when objecting universally one must state a contradiction about that one of the terms proposed that was universal (for example, one must object to the claim that there is not a single scientific knowledge of contraries by saying that there is a single scientific knowledge of all opposites). In this way, it must

119. Reading AΓ.
120. *SE* 171^b14–16, 172^a2–3.

be the first figure; for the term that was universal in relation to the initial subject term becomes the middle term. However, when objecting with a particular statement, one must state a contradiction about something that the premise was universal about—for example, that there is not the same scientific knowledge of the known and the unknown (for "contraries" is universal in relation to these). And it becomes the third figure; for the middle term—that is, "known and unknown"—is what is supposed in part.

Those premises from which it is possible to deduce a contrary result are also those from which we try to state objections. This is why we bring objections only from these figures, for only in them are there opposite deductions (for through the middle figure, it was not possible to deduce affirmatively). In addition, an objection through the middle figure could require more argument—for example, if someone did not grant that A belongs to B because C does not follow it (and this would be clear through other premises). But an objection must not wander off into other matters; rather, the other premise must be evident at once. This is also why it is only from this figure that a sign is not possible.[121]

Other objections also need to be examined, such as those from the contrary, those from what is similar, and those according to belief, and also whether it is possible to get a particular objection from the first figure or a privative objection from the middle figure.

2.27
Likelihoods and Signs

A likelihood and a sign are not the same thing.[122] Instead, a likelihood is an acceptable premise (for what people know happens or does not happen for the most part, or is or is not so for the most part, is a likelihood). For example, "people hate those they envy" or "people show affection for those they love." A sign, however, is intended to be a demonstrative (or necessary) premise or an acceptable one. For whatever is such that if it is, some certain thing is, or if it happened earlier or later the thing in question would have happened, that is a sign of this thing's happening or being. (An enthymeme is a deduction from likelihoods or signs.)

A sign is supposed in three ways, corresponding to the ways the middle term in the figures is supposed. That is, it is supposed either as in the first figure, or as in the middle, or as in the third. For example, proving that a woman is pregnant because she has milk is from the first figure, for the middle term is having milk (let A stand for being pregnant, B having milk, C for woman). "The wise are excellent, for Pittacus was excellent" is through the last figure. A stands for excellent, B stands for the wise,

121. Reading διὸ . . . ἔστιν.
122. Retaining the transmitted order of the text.

C stands for Pittacus. So it is true to predicate both A and B of C, except that people do not state the latter premise because they know it, though they do suppose the former. And "She is pregnant because she is pale" is meant to be through the middle figure: for since paleness follows pregnant women and also follows this woman, people think it has been proved that she is pregnant. A stands for pale, B stands for being pregnant, C stands for woman.

If only one premise is stated, then, it is only a sign, but if the other premise is supposed in addition, it is a deduction. For example, "Pittacus is generous, for the honor-lovers are generous, and Pittacus is an honor-lover." Or again, "The wise are good, for Pittacus was good but also wise." In this way, then, they become deductions. However, the one through the first figure is irrefutable if it is true (for it is universal), while the one through the last is refutable, even if the conclusion is true, because the deduction is neither universal nor in relation to the subject. For even if Pittacus is excellent, other wise men need not be so due to this. The deduction through the middle figure is always and in all ways refutable; for a deduction never comes about when the terms are related in this way. For it is not the case that if a pregnant woman is pale and this woman here is also pale, it is necessary that this woman is pregnant. The truth, then, may exist in all signs, but they have the differences we said.

So, either divide signs in this way and, among them, take the middle term as proof (for we say that what makes us know is proof, and the middle is most like this), or let those from the extreme terms be called "signs" and those from the middle term be called "proofs" (for what is most accepted and most true is what comes through the first figure). **$70^{b}1$**

It is possible to practice physiognomy if it is granted that those affections that arise naturally change the body and the soul at the same time. For perhaps someone who has learned music has changed his soul in a certain way. However, this affection is not one of those that are in us by nature, but instead is like such things as angers and appetites that are natural movements. If this is granted, and also that there is one sign of one thing, and if we are able to grasp the affection and the sign special to each kind of animal, we will be able to practice physiognomy. For if there is some special affection belonging to an indivisible kind, as courage does to lions, there will necessarily be some sign (for body and soul are assumed to be affected together with each other). Let this be having large extremities (which may also belong, though not universally, to other kinds of animals: for the sign is special in this sense, that it is an [affection] special to the kind as a whole, not special to one thing, as we usually use this term). This [affection] will also belong to another kind, and there will be a courageous human or some other animal that will then have the sign; for we assumed there was one sign of one affection. Consequently, if this is how matters stand, and if we are able to collect such signs from those animals which have only one special affection, and each of those has a sign (since it must have *one* sign), we will be able to practice physiognomy.

But if the whole kind has two special affections (as, for example, the lion is courageous and prone to sharing), how can we tell which one of the special signs that follow is the sign of which affection? Perhaps if both belong to something else but not as a whole, and among those cases in which each belongs to something but not entirely, some have one sign and not the other. For if something is courageous but not generous and possesses a certain one of the two signs, it is clear that this is also the sign of courage in the case of the lion.

Physiognomy is by means of a deduction in the first figure in which the middle converts with the first extreme but reaches beyond the third and does not convert with it. For example, courage is A, B stands for large extremities, C is lion. B belongs to everything C belongs to but also to other things. But A belongs to everything B belongs to and not to more things, but instead it converts (if it does not, there will not be one sign of one thing).

POSTERIOR ANALYTICS*

BOOK 1

1.1
Prerequisites for Scientific Knowledge

All teaching and all learning that involve thought come about from already existing knowledge. This is evident if we look at all cases; for the mathematical sciences are acquired in this way and so are each of the other crafts as well. The same holds too in the case of arguments, both those through deductions and those through induction; for it is through things antecedently known that they both do their teaching—the former getting hold of them as if from people who comprehend them, the latter proving the universal through the particular's being clear. Rhetorical arguments also persuade in the same ways; for they are either through paradigms, which is induction, or through enthymemes, which is precisely deduction.[1] **71ª1** 5 10

There are two ways in which it is necessary to have antecedent knowledge: for it is necessary in the case of some things to assume in advance that [each] is; in the case of some to comprehend what the thing being said is, and in the case of some to do both. For example, in the case of everything's being either affirmed or denied truly, that it is so; in the case of the triangle, that it signifies this; in the case of the unit, both—both what it signifies and that it is. For each of these is not clear to us in the same way. 15

It is possible to know when some things are antecedently known and some other things are known at the same time as we acquire our knowledge (for example, everything that falls under a universal of which we have knowledge). For one knew antecedently that every triangle has angles equal to two right angles; but that this [figure] in the semicircle is a triangle is something one came to know at the same time as one was doing the induction.[2] For in some cases learning comes about in this 20

* Translated by C. D. C. Reeve. Text: W. D. Ross, *Aristotelis Analytica Priora et Posteriora* (Oxford, 1964; corrected, 1968), in consultation with J. Barnes, *Aristotle Posterior Analytics* (Oxford, 1994).

1. *Rh.* 1356ª35–ᵇ11.

2. The induction leads from this particular figure T (the one in the circle), which one did not antecedently know, to the universal triangle, of which one antecedently knew that it had angles equal to two right angles, so that at the same time as one does the induction one comes to know that T has angles equal to two right angles (71ª26–27). No deduction is involved, since in this case one does not learn through a middle term (71ª21–24).

way, and it is not through the middle term that the last term comes to be known—this happens when the things are in fact particulars and not said of any underlying subject. But before having done the induction or having got hold of the deduction
25 one must perhaps be said to have scientific knowledge in one way, but in another way not to have it. For if one did not know unconditionally whether it is, how did one know unconditionally that it has angles equal to two right angles? Yet it is clear that one does have scientific knowledge in this way: one has scientific knowledge of it universally, but one does not have scientific knowledge of it unconditionally. Otherwise, the puzzle in the *Meno*[3] will result; for either one will learn nothing or else what one already knows.

30 For one must not speak in the way, at any rate, some people do who try to resolve it: "Do you know every pair to be even, or don't you?" And when one says yes, they put forward some pair of whose existence one was unaware, and so did not think to be even. For they resolve it by saying that people do not know every pair to be even, but rather [only] what they know to be a pair. And yet what they know is precisely
71b1 what they have a demonstration of and made their assumptions about; and they made their assumptions not about everything they know to be a triangle or to be even, but unconditionally about every number and every triangle; for no premise such as "that you know to be a number" or "that you know to be rectilinear" is assumed, but rather it is assumed to hold of every case.

5 But nothing (I think) prevents one from having in one way scientific knowledge of what one learns and in another way being ignorant of it; for what is absurd is not that one knows in some way what one is learning, but that one knows it in this way: in the respect and in the way in which one is learning it.

1.2
Unconditional Scientific Knowledge

We think we have scientific knowledge of a given thing unconditionally (and not—in
10 the sophistical way—coincidentally[4]), when we think we know of the cause due to which the thing is that it is its cause, and also that this does not admit of being otherwise. It is clear, therefore, that having scientific knowledge is something of this sort; for [it is clear in the case of] both those who do not have scientific knowledge and those who do have scientific knowledge: the former think that they are in this condition, while those who know scientifically are in it too. So what there is uncon-
15 ditional scientific knowledge of cannot be otherwise.

Whether there is another way of having scientific knowledge we will discuss later,[5] but we say that in fact we know through demonstration. And by a "demonstration"

3. Plato, *Meno* 80d–e.
4. *Met.* 1026b14–21.
5. 72b19–22.

I mean a scientific deduction; and by "scientific" I mean a deduction in virtue of which, by having it, we know scientifically. Therefore, if having scientific knowledge is the sort of thing we have posited it to be, it is also necessary for demonstrative scientific knowledge to proceed from things that are true, primary, immediate, and better known than, prior to, and causes of the conclusion; for in this way the starting-points will also be proper to what is proved. For while there can be a deduction even without these things, there will not be a demonstration; for it will not produce scientific knowledge.

They must be true, because it is not possible to have scientific knowledge of what is not—for example, that the diagonal [of a square] is commensurable [with its side].

They must proceed from things that are primary and indemonstrable because [otherwise] one will not know scientifically unless one has a demonstration of these things. For to have scientific knowledge of things of which there is a demonstration in a non-coincidental way is to possess the demonstration.

They must also be causes, better known, and prior—causes, because we know something scientifically only when we know the cause; prior, if indeed they are causes; and known antecedently not only in the other way, by being comprehended, but also by one's knowing that they are.

But things are prior and better known in two ways; for it is not the same thing to be prior by nature and prior in relation to us, nor to be better known and better known to us. I call "prior and better known to us" what is closer to perception, "prior and better known unconditionally" what is further away from it. What is most universal is furthest away, while particulars are closest; and these are opposed to each other.

To proceed from things that are primary is to proceed from proper starting-points; for I call the same thing "primary" and a "starting-point." A starting-point of demonstration is an immediate premise, and an immediate one is one to which no other is prior. A premise is one or other part of an assertion, one thing said of one thing. A dialectical premise is one that assumes either part indifferently, while a demonstrative premise is one that determinately posits one part, because it is true. An assertion is either part of a contradiction, while a contradiction is an opposition in which there is intrinsically no intermediate. The part of a contradiction that says something of something is an affirmation, the part that denies something of something is a denial.

An immediate deductive starting-point I call a "posit" if it cannot be proved, but is also not necessary for someone who is going to learn anything to grasp; one that it is necessary for someone to grasp who is going to learn anything at all, I call an "axiom"; for there are some things of this sort; for we are accustomed to use this name especially of such things. A posit that assumes either part of a contradiction (what I mean is that something is or that something is not) is a hypothesis; one without this is a definition. For a definition is a posit; for an arithmetician posits that a unit is what is indivisible in quantity; but it is not a hypothesis, for what a unit is and that it is are not the same.

But since [in order to have scientific knowledge] one must be persuaded of and know a thing by having the sort of deduction we call a "demonstration," and since there is such a deduction when the things from which the deduction comes about are the case, it is necessary for one not only to have antecedent knowledge of the primary things—either all of them or some of them—but also to know them more [than the conclusion]; for the cause due to which F belongs to a given thing always belongs more to it [than F does]—for example, the thing due to which we love something is more loved [than it]. So if indeed we know and are persuaded because of the primary things, we also know those more and are more persuaded of them, since it is because of them that we know and are persuaded of the posterior ones.

But it is not possible to be more persuaded of anything one neither knows nor is better disposed toward than one is of what one knows. But this is what will happen unless someone who is persuaded through demonstration has antecedent knowledge; for it is necessary to be more persuaded of the starting-points—either all of them or some of them—than of the conclusion.

Anyone who, on the other hand, is going to have scientific knowledge through demonstration must not only know the starting-points more and be more persuaded of them than of what is being proved, but also there must be nothing else more
72b1 persuasive or more known to him among the opposites of the starting-points from which there will be a deduction of the contrary error, if indeed anyone who has unconditional scientific knowledge must not admit of being persuaded out of it.

1.3
Regresses and Circles

To some people, because the primary things must be scientifically known, it seems that there is no scientific knowledge, while to others it seems that there is, and indeed that everything has a demonstration. Neither of these views is either true or necessary.

The former, who suppose that there is no scientific knowledge in any other way,[6] claim that we are led back without limit, on the supposition that we cannot have scientific knowledge of what is posterior on the basis of what is prior, if there are no primary things among them. And they are correct; for it is impossible to go through what is without limit. And if it comes to a stop and there are starting-points, these are unknowable since there is no demonstration of them—which alone, they say, is precisely what it is to have scientific knowledge. But if it is not possible to know the primary things, neither is it possible, unconditionally and fully, to have scientific knowledge of what proceeds from them, but only on the hypothesis that those things are the case.

6. I.e., than by demonstration. Reading ἄλλως.

The latter agree about having scientific knowledge; for they say it is only through demonstration, but that nothing prevents there being a demonstration of everything; for it is possible for a demonstration to be circular, that is, from each other.

We, on the other hand, say that not all scientific knowledge is demonstrative, but in the case of the immediates it is non-demonstrative (that this is necessarily so is evident; for if it is necessary to have scientific knowledge of the things that are prior and on which the demonstration depends, and for the immediates to come to a stop at some time, it is necessary for them to be non-demonstrative). This, then, is what we say about these things. And we also say that there is not only scientific knowledge but also some starting-point of scientific knowledge by which we come to know the definitions.

That it is impossible to demonstrate unconditionally in a circle is clear, if indeed a demonstration must proceed from things that are prior and better known; for it is impossible for the same things to be at the same time prior and posterior to the same things, unless they are so in different ways (for example, some prior in relation to us, others unconditionally)—this being precisely the way that induction makes things known. But in that case, unconditional knowing would not have been well defined, but would be twofold. Or else the other sort of demonstration would not be unconditional, since it proceeds on the basis of what is better known to us.

For those who say that there is circular demonstration, the result is not only what has just been stated, but also that they say nothing other than that this is the case if this is the case. But in this way it is easy to prove everything. It is clear that this results when three terms are posited. For it makes no difference whether we say it circles back through many terms or few, or through few or two. For when if A is the case, of necessity B is, and if B is then C is, then if A is the case C will be. If, then, if A is the case, of necessity B is, and if B is then A is (for this is what being circular is), let it be assumed that A is C. Hence to say that if B is the case A is the case is to say that [if B is the case] C is the case. But this is to say that if A is the case, C is the case. But C is the same as A. Hence it follows that those who say that there is demonstration in a circle are saying nothing other than that if A is the case then A is the case. But in this way it is easy to prove anything.

Nonetheless, this is not possible either, except in cases where things follow from each other in the way special affections do. If one thing is assumed, it has been proved that it is never necessary for anything else to be the case (I say "one thing" because neither if one term nor one posit is assumed, [is it necessary]): two posits are the first ones and fewest ones from which it is possible, if indeed it is possible to make deductions. If A follows from B and C, and these follow from each other and from A, in this case it is possible to prove all the postulates from each other in the first figure,

as is proved in the studies concerning deduction.[7] (It has also been proved that in the other figures either there is no deduction or else none about the assumptions.)

But in the case of things that are not counterpredicated it is in no way possible to prove them in a circle, and so since there are few things of this sort in demonstrations, it is evident that it is both empty and impossible to say that there is demonstration of things from each other, and that, because of this, it is possible for there to be demonstration of everything.

1.4
In Every Case, Intrinsically, and Universally

Since what there is unconditional scientific knowledge of cannot be otherwise, what is known scientifically in accord with demonstrative scientific knowledge will be necessary; and it is demonstrative if we have it by having a demonstration. Therefore, a demonstration is a deduction that proceeds from things that are necessary. Therefore, we must get hold of what things, that is, what sorts of things, demonstrations proceed from. But first let us define what we mean by "in every case," by "intrinsically," and by "universally."

I say that what is not such as to hold in some cases but not in others, or at some times but not at others, holds "in every case"—for example, if animal holds of every human, then if it is true to say that this is human, it is true to say that this is animal too, and if it is now true to say the one, it is now true to say the other as well; and if there is a point in every line, it is the same way. A sign of this is that it is how we in fact bring objections when asked whether something holds in every case, if it does not hold either in some case or at some time.

And whatever things belong in the what-it-is of something I say belong "intrinsically"—for example, line belongs intrinsically to triangle and point to line (for their substance is composed of these and these are present in the account that states what the thing is), and also, whatever ones belong to these things, which are present in the account that makes clear their what-it-is—for example, straight belongs to line and so does curved, and odd and even belong to number, and so do prime and composite, and equilateral and oblong;[8] and in all these cases line is present
73b1 in the account that states the what-it-is in the former ones, and number in the latter. Similarly, in other cases too I say that these sorts of things belong "intrinsically" to a given thing, while all that belong in neither way are coincidents—for example, musical and white are coincidents of animal.

7. *APr*. 2.5–7.

8. An equilateral number is n × n; an oblong number is n × m (where n ≠ m). About both sorts of numbers, as about straight and curved lines, things can be demonstrated.

Further, what is not said of some other thing as underlying subject—for example, what is walking is walking by being some other thing, and similarly for what is white,[9] while a substance, and anything that signifies a this something, is precisely what it is without being some other thing. Things, then, that are not said of an underlying subject I call "intrinsic," those that are said of an underlying subject, "coincidents."

Further, in another way, I say that what belongs to a given thing because of itself is "intrinsic," and what does not belong because of itself is a "coincident"—for example, if there was lightning while someone was walking, it was a coincident [of the walking]; for it was not because of the walking that there was lightning, but it was coincidental, we say. But if it was because of itself, it was intrinsic—for example, if something died while being sacrificed, and died during the sacrifice, we say it died because of being sacrificed, but not that it was coincidental that it died while being sacrificed.

Therefore, in the case of what there is unconditional scientific knowledge of, the things said to be intrinsic, in such a way as either to be present in the things of which they are predicated or what *they* are present in, hold because of themselves and are necessary. For it is not possible for them not to belong, either unconditionally or their opposites—for example, as straight and bent to line or odd and even to number. For a contrary is either a privation or a contradictory in the same kind, as, in the case of numbers, even is what is not odd, insofar as it follows. So if it is necessary either to affirm or deny, it is also necessary for what is intrinsic to belong.

Let "in every case" and "intrinsically" be defined in this way.

I say that whatever belongs in every case and intrinsically and insofar as it is itself belongs "universally." Therefore, it is evident that whatever is universal belongs of necessity to the things [it belongs to]. But "intrinsically" and "insofar as it is itself" are the same—for example, point and straight belong to a line intrinsically (for they in fact belong to it insofar as it is a line) and two right angles belong to a triangle insofar as it is a triangle (for a triangle in fact intrinsically has angles equal to two right angles). But something belongs universally whenever it is proved to belong to any random something that is primary. For example, having angles equal to two right angles is not universal to figures (and yet it is possible to prove of some figure that it has angles equal to two right angles, but not of any random figure, nor does one use any random figure in proving it; for a quadrilateral is a figure but does not have angles equal to two right angles), and though any random isosceles triangle does have angles equal to two right angles, it is not primary—on the contrary, triangle is prior. Therefore, if a random primary thing is proved to have angles equal to two right angles (or whatever), then it is to this primary thing that it belongs intrinsically and universally, and the demonstration is intrinsically of this case universally. To the other cases, it applies in a way but not intrinsically—even to the isosceles triangle it does not apply universally, but extends more widely.

9. Rejecting the addition of λευκόν.

1.5
Three Errors about Universal Demonstration

But it must not escape our notice that we often commit errors and that what is proved does not belong primarily and universally in the way that it seems to be proved universally and primarily. We make this mistake either when there is nothing higher to grasp beyond the particular or the particular cases,[10] or there is but it is nameless or applies to things that are different in form, or when what it is proved of is a whole taken as a part; for the demonstration will hold of the parts, and will do so in every case, but nonetheless the demonstration will not hold of this [whole] universally as the primary thing. But I say that a demonstration holds "of this primary thing, as such," whenever it holds of it universally insofar as it is the primary thing.

If, then, someone were to prove that things at right angles do not meet, the demonstration of this might seem to be because it applies to all things at right angles. But it does not, since this [conclusion results] not because the angles are equal in this way[, that is, by both being right angles,] but insofar as they are equal in any way at all. And if there were no triangles other than the isosceles, [having angles equal to two right angles] might seem to belong to an isosceles triangle insofar as it is isosceles.

And that proportionals alternate[11] might seem to apply to numbers insofar as they are numbers, lines insofar as they are lines, solids insofar as they are solids, and times insofar as they are times, as it once used to be demonstrated of these separately, although it is possible, indeed, to prove it of all cases by a single demonstration. But because all these things—numbers, lengths, times, solids—do not constitute a single named [kind] and differ in form from one another, they used to be taken separately. But now it is proved universally; for it did not belong insofar as they are lines, or insofar as they are numbers, but insofar as they are this [unnamed kind], which is assumed to belong universally.

Because of this, even if one proves of each triangle either by one demonstration or by a different one—a separate one for the equilateral and for the scalene and for the isosceles—that each has angles equal to two right angles, one does not yet know that the triangle has angles equal to two right angles, except in the sophistical way,[12] nor does one know it of triangle universally, not even if there is no other triangle beyond these. For one does not know it of a triangle insofar as it is a triangle, or even of every triangle (except numerically—one does not know it of every triangle in virtue of its form, even if there is no triangle that one does not know).

So when exactly does one not know universally, and when exactly does one know unconditionally? It is clear, indeed, that we would know [that a triangle has angles equal to two right angles] if being were the same for triangle and for equilateral

10. Reading ἢ τὰ καθ' ἕκαστα.
11. *NE* 1113ᵇ5–7.
12. 71ᵇ10.

triangle, either for each or for all [and we had proved that an equilateral triangle has angles equal to two right angles]. But if their being is not the same but different, and it belongs insofar as the triangle is a triangle, we do not know it. Does it belong insofar as it is a triangle or insofar as it is isosceles? And when does it belong to it as primary thing? And of what does the demonstration hold universally? It is clear that it would belong to a primary thing when other things have been abstracted. For example, having angles equal to two right angles will belong to an isosceles bronze triangle, but will also do so when being bronze and being isosceles have been abstracted. But not when figure and limit are.[13] But they are not the primary thing. Of what, then, [does it hold universally] as the primary thing? If it is "triangle," it is in virtue of this that it belongs to others, and it is of this that the demonstration holds universally.

1.6
Scientific Premises Are Intrinsic Ones

If, then, demonstrative scientific knowledge proceeds from necessary starting points (for what one knows scientifically cannot be otherwise) and the things that belong intrinsically to things are necessary (for some belong in the what-it-is; while others are predicated of things that themselves belong in their what-it-is, to which one or other of the opposites must belong), it is evident that it is from some things of this sort that demonstrative deduction will proceed; for everything belongs in this way or coincidentally, and coincidents are not necessary.

Either, then, it must be stated like this or else by positing as a starting-point that the demonstration is necessary,[14] that is, that if something has been demonstrated it cannot be otherwise—the deduction, therefore, must be from necessities. For from truths it is possible to deduce without demonstrating, but from necessities it is not possible to deduce otherwise than by demonstrating; for this is in fact a mark of demonstration.

A sign that demonstration proceeds from necessities is that this is how we bring objections against those who think they are demonstrating (that it is not necessary), if we think that—either in general or, at any rate, for the sake of the argument—it admits of being otherwise.

It is also clear from these considerations that those people are simpleminded who think that if a premise is acceptable and true they grasp the starting-points in the correct way—for example, the sophists who think that to know scientifically is to have scientific knowledge.[15] For a starting-point is not what is acceptable or not,[16]

13. Because a triangle is by definition a plane figure limited (or bounded) by three straight lines.
14. Reading ἀναγκαῖον.
15. Plato, *Euthydemus* 277b, *Theaetetus* 197a.
16. Reading ἔνδοξον ἢ μὴ ἀρχή.

but what is primary in the kind about which something is being proved; and not everything true is proper [to the kind].

That the deduction must proceed from necessities is clear from the following too. For if someone, in a case where there is a demonstration, does not have an account of the why, he is not a scientific knower, and if it might be that A belongs of necessity to C, but B, the middle term through which this was demonstrated, does not belong of necessity, then he does not know why [A belongs]. For it does not hold because of the middle; for the middle admits of not being [the case], while the conclusion is necessary.

Further, if someone does not know something now, even though he has an account of it and is preserved, and the thing is preserved, and he has not forgotten it, then he did not know it earlier either. But the middle term might pass away if it is not necessary. So he will have the account, since he is preserved and the thing is preserved, but he does not know it. Therefore, he did not know it earlier either. But if the middle term has not passed away, though it is possible for it to pass away, the result will be possible and admit of obtaining. But in such circumstances it is impossible to have knowledge.

75a1 When the conclusion holds of necessity, nothing prevents the middle term through which it was proved from being non-necessary. For it is possible to deduce a necessity from non-necessities, just as it is to deduce a truth from non-truths. But when the middle term holds of necessity, the conclusion holds of necessity too, just as from true premises the conclusion is always true (for let A be predicated of B of necessity, and B of C; therefore for A to belong to C is also necessary). But when the conclusion is not necessary, the middle term cannot be necessary either (for let A belong to C not of necessity, and let A belong to B and B to C of necessity; A will then belong to C of necessity too; but it was assumed not to).

Therefore, since if someone has demonstrative scientific knowledge of something, it must hold of necessity, it is clear that the demonstration he has must be through a middle term that is necessary too. Otherwise, he will not know scientifically either why or that it is necessary for that thing to hold, but either he will think he knows, though he does not (if he takes as necessary what is not necessary), or he will not even think that he does (equally whether he knows the that through middle terms or the why through immediates).

But there is no demonstrative scientific knowledge of coincidents that are not intrinsic (in the way in which intrinsic coincidents were defined). For we cannot prove the conclusion of necessity; for it is possible for what is coincidental not to belong (for that is the sort of coincident I am talking about). And yet one might perhaps raise a puzzle as to what the point is of asking for premises about these things, if the conclusion is not necessary. For it is no different than if someone asked random questions and then asserted the conclusion. But one must ask questions not on the supposition that the answers make the conclusion necessary, but because it is necessary for anyone who gives these answers to assert the conclusion, and to assert it truly, if the answers truly hold.

But since in each kind whatever belongs to each thing intrinsically, and insofar as it is that thing, belongs of necessity, it is evident that scientific demonstrations are concerned with things that belong intrinsically and proceed from such things. For coincidents are not necessary, and so it is not necessary to know why a conclusion derived from them holds, not even if it does always but not intrinsically—for example, in deductions through signs. For something might belong intrinsically but one will not scientifically know that it does, or why it does. (To have scientific knowledge of the why is to have scientific knowledge through the cause). Therefore, it is because of itself that the middle term must belong to the third term, and the first to the middle.

1.7
Demonstration Stays within a Single Kind

Therefore, it is not possible to prove anything by crossing over from one kind [to another]—for example, proving something geometrical by arithmetic. For there are three things in demonstrations: one, what is being demonstrated—the conclusion (this is what belongs intrinsically to some kind); another, the axioms (axioms are the things from which the demonstration proceeds); third, the underlying kind whose affections and intrinsic coincidents the demonstration makes clear. **$75^{b}1$**

The things from which the demonstration proceeds may be the same, but in cases where the kinds are different, as with arithmetic and geometry, it is not possible to apply an arithmetical demonstration to the coincidents of magnitudes, unless the magnitudes are numbers. (How this is possible in certain cases will be stated later.[17]) On the contrary, an arithmetical demonstration always contains the kind with which the demonstration is concerned, and the other demonstrations likewise. So if a demonstration is to cross over, it is necessary for the kind to be the same either unconditionally or in some respect. Clearly, it is impossible otherwise; for the extreme and middle terms must be from the same kind; for if they are not intrinsic, they will be coincidents.

That is why it is not possible to prove by geometry that there is one science of contraries, nor that two cubes make a cube; nor is it possible to prove by one science what belongs to a different one, except when they are so related to one another that one falls under the other—as, for example, optics is to geometry and harmonics to arithmetic. Nor is it even possible to prove by geometry anything that belongs to lines but not insofar as they are lines or insofar as they proceed from the starting-points special to geometry—for example, whether the straight line is the most beautiful or whether it is contrary to the curved one. For these things belong to them not as their special kind, but as something common.

17. $76^{a}9$–15, 23–25, $78^{b}34$–$79^{a}16$.

1.8
Demonstration Is of Eternal Things

It is evident too that if the premises from which a deduction proceeds are universal, then it is also necessary for the conclusion of such a demonstration—that is to say, an unconditional demonstration—to be eternal. Therefore, there is no demonstration of what is capable of passing away and no unconditional scientific knowledge of it either, though there is a sort that is coincidental, because it does not hold of it universally,[18] but at some time and in some way.

But when there is such a demonstration, one premise or the other must be non-universal and capable of passing away: capable of passing away, because when it is the case the conclusion will also be the case; non-universal, because it will apply in certain respects, but in others it will not.[19] So that it is not possible to deduce that anything holds universally, but only that it holds now.

It is the same way too as regards definitions, since in fact a definition is either a starting-point of demonstration, a demonstration differing in arrangement, or a sort of conclusion of a demonstration.[20]

Demonstrations and sciences concerned with things that come about often—for example, eclipses of the moon—clearly hold always, insofar as they apply to this sort of thing, but they are particular insofar as they do not always hold [of these things]. And as with eclipses, so in the other cases.

1.9
Special and Indemonstrable Starting-Points

Since it is evident that it is not possible to demonstrate a given thing except from its own starting-points, if what is being proved belongs to it insofar as it is that thing, it is not possible to have scientific knowledge of this [simply] from having proved it from premises that are true, indemonstrable, and immediate. Otherwise, it will be possible to prove things in the way Bryson proved the squaring of the circle. For such arguments prove things in virtue of some common feature that belongs to something else as well. That is why the arguments also apply to other things that are not in the same kind. Hence one does not have scientific knowledge of that thing insofar as it is that thing, but coincidentally; for otherwise, the demonstration would not apply to another kind as well.

We scientifically know a given thing non-coincidentally when we know it in virtue of that in virtue of which it belongs, from the starting-points of that thing insofar as

18. Reading καθόλου.
19. Reading ᾧ μὲν ἔσται ᾧ δ’ οὐκ ἔσται ἐφ’ ὧν.
20. 2.10.

it is that thing—for example, knowing that [a triangle] has angles equal to two right angles when we know that it belongs intrinsically to [the triangle, and derive this] from its starting-points. So if this also belongs intrinsically to what it belongs to, it is necessary for the middle term to be in the same kind.

Otherwise, it will be like harmonics [being proved] through arithmetic. Such things are proved in this way, but there is a difference. Such things are proved in this way, but there is a difference. For the *that* is the concern of one of the two sciences (for the underlying kind is different), while the *why* is the concern of the higher one, to which the affections belong intrinsically. So from these considerations too it is evident that it is not possible to demonstrate a given thing unconditionally except from its own starting-points. But the starting-points of these have a common feature.

But if this is evident, it is also evident that it is not possible to demonstrate the starting-points special to a given thing [from other ones]; for then those starting-points will be starting-points of all things, and the science of them will have control over all things. For in fact the one who knows from the higher causes knows more scientifically; for one knows from prior causes when one knows from uncaused causes. So if he knows more fully, in fact, most fully, then that science will also be more fully, in fact, most fully, a science. But a demonstration does not apply to another kind, except, as was said,[21] in the way that geometrical demonstrations apply in the case of mechanics or optics and as arithmetical ones do in the case of harmonics.

It is difficult to know whether one knows or not. For it is difficult to know whether or not we know from the starting-points of a given thing. (For that is precisely what knowing is.) But we think that we have scientific knowledge of something if we have a deduction of it from things that are true and primary. But this is not so; instead, it must be in the same kind as the primary things.

1.10
The Starting-Points in a Kind

I call "starting-points" in a given kind those things for which it is not possible to prove that they hold. What both the primary things and the things that proceed from them signify is assumed; but that they hold, it is necessary to assume for the starting-points and to prove for the rest—for example, it is necessary to assume what a unit is or what straight and triangle are, and also that a unit and magnitude are, but to prove the other things.

Among the things used in the demonstrative sciences, some are special to each science while others are common, but common by analogy, since something is useful, in fact, [only] to the extent that it applies to the kind that falls under the science: special

21. 75^b14–17, 76^a9–15.

ones—for example, that a line is such-and-such, and straight is such-and-such; common ones—for example, that if equals are subtracted from equals, the remainders are equal. Each of these is sufficient to the extent that it applies to the kind; for it will produce the same result even if one assumes it to hold not of everything but only of
76b1 magnitudes, or, in the case of the arithmetician, of numbers.

Also special are the things that are assumed to be, and concerning which the science gets a theoretical grasp on what belongs to them intrinsically—for example, as regards units, arithmetic, and as regards points and lines, geometry. For they assume that these things are and that they are this. As for the intrinsic affections of these, they assume what each signifies—for example, arithmetic assumes what odd, even, square, or cube signifies, while geometry assumes what incommensurable, broken line, or oblique line signifies; but that these things are, they prove through the common things and from what has been demonstrated. And astronomy does the same thing.

For every demonstrative science is concerned with three things: what it posits to be (these constitute the kind on whose intrinsic affections it gets a theoretical grasp); the common so-called axioms (that is, the primary things from which the demonstrations proceed); and third, the affections, concerning which it assumes what each signifies. But certainly nothing prevents some sciences from disregarding some of these—for example, not hypothesizing that the kind is, if it is evident that it is (for that number is, and that hot and cold are, is not clear in the same way), nor need they assume what the affections signify, insofar as these are clear. In the same way, in the case of the common things, they need not assume what subtracting equals from equals signifies, because it is known. Nonetheless, by nature, at any rate, there are these three things: that concerning which the science proves things, the things it proves, and the things from which it proves them.

What must be the case because of itself, and one must believe to be the case, is neither a hypothesis nor a postulate. For demonstration is not directed toward external argument, but toward the one in the soul, since deduction is also not [so directed]. For it is always possible to object to external argument, but not always to internal argument. But whenever one assumes something provable without having proved it oneself, if the learner believes this assumption to be so, one is hypothesizing it (and it is a hypothesis not unconditionally but only in relation to the learner). But if one assumes the same thing when the learner has either no belief or even the contrary belief, he makes a postulate. And it is in this that a hypothesis and a postulate differ; for a postulate is contrary to the learner's belief, or is something which, though demonstrable, one assumes and uses without demonstrating.

Terms are not hypotheses (for they are not said to be or not to be anything), while hypotheses are among the premises, while terms need only be comprehended. But this is not hypothesizing (unless one is going to say that even hearing is hypothesizing). On the contrary, hypotheses are among the things which, if they are the case, then the conclusion comes about due to their being the case.

Nor does the geometer hypothesize falsehoods, as some people have claimed,[22] saying that one must not make use of falsehoods, and that the geometer speaks falsely when he says of a line that is not a foot long that it is a foot long or that a drawn line is straight when it is not straight. But the geometer does not conclude anything from the line's being as he himself has described it, but from the things that are proved by means of these figures.

Further, all postulates and hypotheses are either universal or particular, and terms are neither of these.

1.11
Platonic Forms; Common Things

There is no necessity for there to be Forms, or one thing beyond the many, if there is to be demonstration. It is necessary, however, for it to be true to say that one thing holds of many; for if this is not the case, there will be no universal. And if there is no universal, there will be no middle term, so that there will be no demonstration either. Therefore, there must be one and the same thing, and not a homonymous one, that holds of many things.

No demonstration assumes that it is not possible to affirm and deny at the same time—unless the conclusion too must be proved in this way. On the contrary, it is proved by assuming that it is true to affirm the first term of the middle, and that it is not true to deny it. As for the middle term, it makes no difference if one assumes that it is and that it is not, and likewise for the third term. For if one is given something of which it is true to say that it is human, if it is also true to say that it is not-human, then provided only that it is true to say that a human is an animal and not a not-animal, it will be true to say that Callias, even if he is also not-Callias, is nonetheless an animal and not a not-animal. The cause of this is that the first term is said not only of the middle term, but also of something else, because it holds of many; so that even if the middle term both is itself and is not itself,[23] it makes no difference to the conclusion.

Demonstration by reducing to the impossible, for its part, assumes that all things are affirmed or denied, and these not always universally, but to the extent that is sufficient—and it is sufficient when it applies to the kind. (By "applies to the kind" I mean the kind on which one brings the demonstrations to bear, as was also stated previously.[24])

All the sciences share with one another the common things (by "common things" I mean the ones people use as the things from which demonstration proceeds, but not what they prove things about nor what they prove), and dialectic shares these with

22. E.g., Protagoras (*Met.* $997^{b}35$–$998^{a}4$).
23. I.e., so that the middle term is both F and not F.
24. $76^{a}42$–$^{b}2$.

all of them, as would anything that tried to prove the common things in a universal way—for example, that everything is affirmed or denied, or that equals subtracted from equals leave equals, or other things of this sort. But dialectic is not concerned in this way with any determinate sorts of things, or with any one single kind. For if it were, it would not ask questions; for when one is demonstrating it is not possible to ask questions because, when opposites are given, one cannot prove the same thing. This was proved in the studies concerning deduction.[25]

1.12
The Role of Questioning in Science

If a deductive question is the same thing as a premise that is one part of a contradiction, and in each science there are premises from which a deduction proceeds in each one, then there will be such a thing as a scientific question—one from which a deduction proper to each science proceeds. Therefore, it is clear that not every question will be geometrical (or medical, and similarly in the other cases), but only those from which something with which geometry is concerned can be proved, or which can be proved from the same things as in geometry, as with optics. And similarly in the case of the others. And as regards these, an argument must be given from the starting-points and conclusions of geometry, while to have to give an argument concerning the starting-points is not a task for a geometer insofar as he is a geometer. And similarly in the case of the other sciences. Therefore, one must not ask each scientist every question, nor must he have to answer every question he is asked about each thing, but only those determined by his science. If one discusses in this way with a geometer insofar as he is a geometer, it is evident that one does so correctly if one proves something from these. Otherwise, one will do so incorrectly. And it is clear that one does not refute a geometer either, except coincidentally. So one must not discuss geometry among those ignorant of geometry; for one who discusses defectively will escape detection. And the situation is the same in the case of the other sciences too.

But since there are geometrical questions, are there also non-geometrical questions? And for each science, with respect to what sort of ignorance are there [the equivalents of] geometrical questions? And is a deduction in accord with ignorance one that proceeds from opposite ones [to geometry], or is it one that is fallacious, though in accord with geometry, or is it one proceeding from another craft? For example, is a musical question about geometry non-geometrical, while thinking that parallel lines meet is geometrical in one way and non-geometrical in another? For being non-geometrical is twofold, like being non-rhythmical, and in one way being non-geometrical is not possessing the science, and in another possessing it

25. *APr.* 57a36–b17.

defectively. And it is this ignorance—the one that proceeds from the relevant sorts of starting-points—that is contrary [to the science]. But in mathematics, the fallacious argument is not possible in the same way, because the middle term is always twofold; for something is said of all of it, and, again, it is said of all of something else (but all is not said of what is predicated).[26]

But while it is possible to see, as it were, these things by the understanding, in [external] arguments, they escape notice.[27] Is every *kuklos* a figure? (If one draws one, [the question] is clear.) Then, are epic poems a *kuklos*? (It is evident that they are not.)[28]

One must not bring an objection to an argument if the premise is inductive. For just as there is no premise that does not apply to several things (for otherwise it will not apply to all, and a deduction proceeds from universal premises), it is clear that there is no objection either. For premises and objections are the same; for what one brings as an objection may become a premise, either demonstrative or dialectical.

But it happens that some people argue non-deductively because they assume things that follow both terms—for example, Caeneus in fact does so when he says that fire consists in multiple proportion;[29] for fire is in fact generated quickly, he says, and so is this proportion. But in this way there is no deduction; though there is one if multiple proportion follows fastest proportion and the fastest proportion in a movement follows fire.

Sometimes, then, it is not possible to produce a deduction from what has been assumed, and sometimes it is, but it is not seen.

If it were impossible to prove truth from falsehood, to do analytics would be easy; for then there would of necessity be conversion. For let A be something that is the case; and if A is the case, then these things, which I know to be the case, are the case (call them B). Therefore, from these I will prove that A is the case. Conversion is more common in mathematics because mathematics assumes nothing coincidental—and in this respect too it differs from dialectics—but [only] definitions.

A deduction increases not through the middle terms but by adding—for example, A is said of B, B of C, and C, again, of D, and so on without limit. Also laterally—for example, A is said both of C and E. For example, A is limited (or even unlimited) number, B limited odd number, and C odd number: therefore, A is said of C. D is limited even number, E even number: therefore, A is said of E.

26. B belongs to every A, C belongs to every B, but though C therefore belongs to every A, every C is not said to belong to every A.
27. $76^b25–27$.
28. A *kuklos* can be either a circle or a cycle. The epic poems are the latter, but not the former.
29. I.e., geometrical proportion.

1.13
The That and the Why

Having scientific knowledge of the that and of the why are different.

First, they are different within the same science and in two ways. In one way, if the deduction does not proceed through immediates (for the primary cause is not grasped, but the scientific knowledge of the why comes about in virtue of the primary cause). In a second way, if it does proceed through immediates, but not through the cause, but rather through the more known of the converting terms. For, among counterpredicated terms, nothing prevents the term that is not the cause from sometimes being more known, so that demonstration will proceed through it.

For example, a demonstration that the planets are near due to their not twinkling. Let C be planets, B not twinkling, and A being near. It is true to say B of C, for the planets do not twinkle. But also to say A of B, for what does not twinkle is near (let this be assumed through induction or through perception). It is necessary, then, for A to belong to C, so that it has been demonstrated that the planets are near. This deduction, then, is not of the why but of the that; for it is not because they do not twinkle that they are near, but because they are near that they do not twinkle.

It is also possible for the latter to be proved through the former, and then the demonstration will be of the why. For example, let C be planets, B being near, and **78b1** A not twinkling. Then B again belongs to C and A to B, so that A also belongs to C. And the deduction is of the why. For the primary cause has been grasped.

Again, [take] the way people prove that the moon is spherical through its waxing—for if what waxes in this way is spherical, and the moon waxes [in this way], it is evident that it is spherical. In this way, then, one has produced a deduction of the that, while if the placement of the middle term is reversed, of the why.[30] For it is not because of its waxings that the moon is spherical, but rather it has waxings of this sort because it is spherical. Let the moon be C, spherical B, and waxing A.

But in cases where the middle terms do not convert and the one that is not the cause is more known, the that is proved but not the why.

Further, there are cases where the middle is placed outside. For in these too the demonstration is of the that and not of the why. For the cause is not stated. For example, why does a wall not breathe? Because it is not an animal. For if this were the cause of not breathing, then being an animal would have to be the cause of breathing—that is, if the negation is the cause of something's not belonging, the affirmation is the cause of its belonging (as in this case: if the cause of not being healthy is the hot and cold elements not being proportional, their being proportional is the cause of being healthy); similarly, if the affirmation is the cause of something's belonging, the negation is the cause of its not belonging. But in the case exhibited, what was stated does not occur; for not every animal breathes. A deduction of this sort of cause comes

30. I.e., if instead of B holds of A, one has A holds of B.

about in the middle figure. For example, let A be animal, B breathing, and C wall. A belongs to every B (for all animals breathe), and to no C, so that B too belongs to no C. Therefore, a wall does not breathe.

These sorts of causes seem like statements that go too far (that is, when one states the middle term at too great a remove)—for example, like Anacharsis' statement that among the Scythians there are no pipe-playing girls, for there are no vines either.

With regard to the same science, then, and with regard to the position of the middle terms, these are the differences between a deduction of the that and one of the why.

The why and the that differ, however, in another way by each of them being theoretically grasped by a different science. These are the cases that are related to each other in such a way that one falls under the other—for example, as optics is related to geometry, mechanics to solid geometry, harmonics to arithmetic, and stargazing to astronomy. Some of these sciences have pretty much the same name—for example, mathematical and nautical astronomy, and mathematical harmonics and acoustical harmonics. For in these cases it is for the perceptual scientists to know the that, and for the mathematical ones to know the why; for the latter possess the demonstrations of the causes, and often they do not know the that, just as people who get a theoretical grasp on the universal often do not know some of the particulars through lack of observation. These are things that, though they are something else in their substance, furnish forms. For mathematics is concerned with forms; for they are not said of any underlying subject; for even if the geometrically treatable ones[31] are said of an underlying subject, still it is not insofar as they are said of an underlying subject that they are such.

There is another science—that concerned with the rainbow—that is related to optics as optics is to geometry. For here it is for a natural scientist to know the that, and for a student of optics—either unconditional or mathematical—to know the why. And in fact many sciences that are not subordinate to each other are related in this way—for example, medicine to geometry; for that circular wounds heal more quickly is for the doctor to know, but it is for the geometer to know why.

1.14
The Superiority of the First Figure

Among the [syllogistic] figures, the first is most scientific. For the mathematical sciences carry out their demonstrations through this figure—for example, arithmetic, geometry, and optics—and so do pretty much all those that investigate the why. For a deduction of the why is carried out through this figure, whether it is in general[32]

31. Reading γεωμετρητά.
32. I.e., in all cases.

or for the most part and in most cases. That is also why it is the most scientific; for getting a theoretical grasp on the why is most in control of knowledge.

Next, only through this figure is it possible to hunt down scientific knowledge of the what-it-is. For in the middle figure there are no positive deductions, but scientific knowledge of the what-it-is is scientific knowledge of an affirmation; and in the last figure, although affirmative deductions do occur, they are not universal, while the what-it-is is of universals; for it is not [merely] in some place that a human being is a two-footed animal.

Further, this figure has no need of the others; but they are filled up and increased through it, until they arrive at the immediates.

It is evident, then, that the first figure is most in control of scientific knowledge.

1.15
Negative Propositions

Just as it is possible for A to belong to B indivisibly, so it is also possible for it to not belong indivisibly. By belonging or not belonging "indivisibly" I mean that there is no middle term for them; for then the belonging or not belonging will not hold in virtue of something else.

When, then, either A or B is included in some whole, or when both are, it is not possible for A to not belong to B in the primary way.[33] For let A be in the whole C. Then if B is not in the whole C (for it is possible for A to be included in some whole and for B not to be included in it), there will be a deduction of A's not belonging to B.
79b1 For if C belongs to every A and to no B, A belongs to no B. Similarly, if B is included in some whole—for example, in D. For D belongs to every B and A to no D, so that A will, by deduction, belong to no B. It will be proved in the same way if both terms are included in some whole.

But that it is possible for B not to be included in some whole that A is included in, or, again, for A not to be included in one that B is included in, is evident from columns of terms that do not overlap each other. For if nothing in the column ACD is predicated of anything in the column BEF, but A is included in the whole H, which is in the same column, it is evident that B will not be in H; for then the columns will overlap. Similarly, if B is included in some whole.

But if neither is included in a whole and A does not belong to B, it is necessary for A to indivisibly not belong. For if there will be a middle term, it is necessary for one or the other of them to be included in some whole. For the deduction will be either in the first figure or in the middle one. If, then, it is in the first figure, B will be included in some whole (for the premise in relation to this term [as subject] must be affirmative), while if it is in the middle figure, one or the other of them will be in

33. I.e., indivisibly or immediately.

some whole; for a deduction comes about when the privative is assumed in relation to either of the two. But if both are negative, there will not be a deduction.

It is evident, then, that it is possible for one thing to indivisibly not belong to another, and we have said when and how it is possible.

1.16
Ignorance and Error in Immediate Cases

Ignorance, not of the sort that is so-called with respect to a negation, but with respect to a disposition, is error that comes about in a deduction. And in the cases of things that belong or do not belong in the primary way, this comes about in two ways: either when one simply accepts that it belongs or does not belong or when one accepts the supposition through a deduction. Error in a simple supposition is simple, but in supposition through a deduction it is of several sorts.

For let A belong to no B indivisibly. Then if one deduces that A belongs to B by taking C as a middle term, one will have erred through a deduction. And it is possible for both premises to be false, but it is possible for only one of them to be false. For if neither A belongs to any C nor C to any B, but the reverse of each has been assumed, both will be false. But it is possible for C to be related to A and B in such a way that it neither falls under A nor belongs universally to B. For it is impossible for B to be included in any whole (for A was said to not belong to it in the primary way), and it is not necessary for A to belong universally to everything there is. So both premises will be false.

But it is also possible to take one of the premises as true—not, however, either one at random, but rather AC. For premise CB will always be false, because B is not **80^a1** included in anything, while AC may be true—for example, if A belongs indivisibly to both C and B (for when the same thing is predicated in the primary way of several things, neither will be included in the other). But it makes no difference if it belongs non-indivisibly.

Error about something belonging comes about in these ways and only in these (for there is not, as we saw,[34] a deduction of belonging in any other figure), but error about something not belonging comes about both in the first and in the middle figure.

First let us say in how many ways it comes about in the first figure and how the premises hold. Error is possible when both are false—for example, if A belongs indivisibly both to C and to B. For if A is assumed to belong to no C and C to every B, the premises are false. But it is also possible when one—either one—is false. For it is possible for AC to be true and CB false—AC true because A does not belong to everything there is, CB false because it is impossible for C to belong to B when A belongs to no C (for then the premise AC will no longer be true; at the same time, if

34. *APr*. 1.5–6.

both are true, the conclusion will be true too). But it is also possible for premise CB to be true while the other is false—for example, if B is included both in C and in A; for then it is necessary for one of the two to fall under the other, so that if one assumes that A belongs to no C the premise will be false.

It is evident, then, that the deduction will be false both when one premise is false and when both are false.

In the middle figure it is not possible for both premises to be false as wholes. For when A belongs to every B, it will not be possible to get hold of a term that will belong to all of the one and none of the other. But one must assume premises in such a way that this term belongs to one and does not belong to the other, if indeed there is to be a deduction. If, then, they are false when assumed in this way, it is clear that when they are assumed in the contrary way, they will hold in the reverse one. But this is impossible.

But nothing prevents each of them from being false in part—for example, C might belong both to some A and to some B; for if it is assumed to belong to every A and to no B, both premises will be false—not, however, as wholes but in part. And if the privative is posited in the reverse way, the same holds.

And it is possible for one—in fact, either one—to be false. For what belongs to every A also belongs to [every] B. If, then, C is assumed to belong to the whole of A and to not belong to the whole of B, CA will be true but CB false. Again, what belongs to no B will not belong to every A either; for if it belongs to A, then to B too. But it was assumed not to belong to B. If, then, C is assumed to belong to the whole of A and to no B, the premise CB is true and the other one false.

Similarly, if the privative is transposed. For what belongs to no A will not belong to any B either. If, then, C is assumed not to belong to the whole of A and to belong to the whole of B, the premise CA will be true and the other one false. And, again, to assume that what belongs to every B belongs to no A is false. For if it belongs to every B, it is necessary for it also to belong to some A. If, then, C is assumed to belong to every B and to no A, CB will be true and CA false.

It is evident, then, that there will be a deduction leading to error in the case of indivisible premises when both are false and also when only one of them is.

1.17
Error in Non-immediate Cases

In the case of things that belong non-indivisibly, when the deduction of the falsehood comes about through the proper middle term, it is not possible for both premises to be false, but only the one in relation to the major extreme. (I call "a proper middle term" one through which the deduction of the contradictory[35] comes about.) For

35. I.e., of the false conclusion.

let A belong to B through a middle term C. Since, then, CB must be assumed as affirmative if a deduction is to come about, it is clear that this will always be true; for it does not convert. But premise AC is false; for it is when this is converted that the contrary deduction comes about.

Similarly, if the middle term is taken from another column—for example, D, if it is both included in the whole of A and predicated of every B; for it is necessary for the premise DB to stand and for the other to be converted, so that the former is always true and the latter always false. And this sort of error is pretty much the same as that through a proper middle term.

But if it is not through the proper middle term that the deduction comes about, when the middle falls under A and belongs to no B, it is necessary for both premises to be false. For the premises must be assumed in a way contrary to the way they actually hold, if there is going to be a deduction; but assumed in this way, both come out false. That is, if A belongs to the whole of D and D to no B; for when they are converted there will be a deduction and both premises will be false.

But when the middle term—for example, D—does not fall under A, AD will be true and DB false. For AD is true because D was not included in A, while DB is false because, if it were true, the conclusion would be true; but it was [assumed to be] false.

When error comes about through the middle figure, it is not possible for both premises to be false as wholes (for when B falls under A, it is not possible for any term to belong to all of one and none of the other, as was also said earlier[36]), but it is possible for one—in fact, either one—[to be false as a whole]. For if C belongs to both A and B, then if it is assumed to belong to A but not to B, CA will be true and the other premise false. Again, if C is assumed to belong to B and to no A, CB will be true and the other premise false.

If the deduction of the error is privative, we have said[37] when and through what sorts of things there will be error. But if it is affirmative, when it is through the proper middle term, it is impossible for both premises to be false; for it is necessary for premise CB to stand, if indeed there is to be a deduction, as was also said previously.[38] So AC will always be false; for this is the one that converts.

It is the same way if the middle term is taken from another column, as was also said[39] in the case of privative error; for it is necessary for DB to stand and for AD to convert, and the error is the same as before.

But when the deduction is not through the proper middle term, if D falls under A, this premise will be true and the other one false; for it is possible for A to belong to several things that do not fall under each other. But if D does not fall under A, it is clear that this premise[40] will always be false (for it was assumed as affirmative), while premise

36. 80^a27–33.
37. 80^b18–32.
38. 80^b23.
39. 80^b26.
40. I.e., AD.

DB admits of being true and also of being false. For nothing prevents A from belonging to no D and D to every B—for example, animal to [no] scientific knowledge, scientific knowledge to [every] music. Nor does anything prevent A from belonging to no D and D to no B. It is evident, then, that if the middle term does not fall under A, it is possible for both premises to be false, or for one—the first—to be false.[41]

It is evident, then, in how many ways and due to what things it is possible for errors to occur in deduction, both in the case of immediate premises and in the case of conclusions proved through deduction.

1.18
Perceptual Ignorance

It is also evident that if some perception is wanting, some scientific knowledge is also wanting, and this knowledge is impossible to obtain, since we learn either by induction or by demonstration; demonstration is from universals and induction is from particulars, and it is impossible to get a theoretical grasp on universals except through induction (since even the things we speak of as a result of abstraction will be made known [only] through induction, that some belong to each kind, even if they are not separable insofar as each is such as it is). But to make an induction without having perception is impossible; for perception is of particulars, and it is not possible for scientific knowledge to grasp these; for it cannot do so either from universals without induction or through induction without perception.

1.19
The Number of Premises and the Sorts of Predication

Every deduction proceeds through three terms. One sort is able to prove that A belongs to C because it belongs to B and B belongs to C, and the other sort is privative, having as one premise that something belongs to something else, and the other that something does not belong. It is evident, then, that these are the starting-points—that is, the ones that are called "hypotheses"; for it is necessary to assume these in this way in order to prove things—for example, that A belongs to C through B, and, again, that A belongs to B through another middle term, and that B belongs to C in the same way.

For those who make deductions in accord with belief, that is, only dialectically, it is clear that the only thing that must be investigated is whether the deduction proceeds from the most acceptable premises possible, so that even if there is not in truth any middle term between A and B, but there is believed to be one, anyone who makes

41. Reading φανερὸν οὖν . . . καὶ τὴν προτέραν.

a deduction through it has deduced dialectically. But with a view to truth, one must investigate by proceeding from what actually belongs. It is like this: since it is possible for one thing to be predicated of another non-coincidentally—by "coincidentally" I mean, for example, when we say that this white thing is a human being, not meaning the same as when we say that the human being is white. For the human being is not white by being another thing, while the white thing is a human being because the human being is coincidentally white—it is possible, then, that some things are such that they are predicated intrinsically.

Let C, then, be such that it no longer belongs to something else, and let B belong to it in the primary way (that is, there is no other thing between them). And, again, let E belong to F in the same way, and F to B. Is it necessary for this to come to a stop, or is it possible for it to go on without limit?

Again, if nothing is predicated intrinsically of A and A belongs to H in the primary way, and to nothing prior in between, and if H belongs to G, and this to B, is it necessary for this too to come to a stop, or is it possible for it too to go on without limit? This case differs from the previous one in that the first is of whether it is possible, by starting from something that belongs to no other thing while something else belongs to it, to go on upward without limit; while in the second, starting from something that belongs to something else while nothing is predicated of it, one investigates whether it is possible to go on downward without limit.

Further, is it possible for there to be unlimited intermediates if the extremes are determinate? I mean, for example, if A belongs to C, and B is a middle term between them, and between B and A there are others, and others between these, is it possible for even these to be unlimited, or is it impossible? This is the same as investigating whether demonstrations can go on without limit and whether there can be demonstration of everything, or whether terms are bounded at each other.[42]

I say the same thing too in the case of privative deductions and premises—for example, if A does not belong to any B, either it does not belong to B in the primary way or else there will be some intermediate to which—as prior—it does not belong (for example, G, which belongs to every B), and, again, to yet another term prior to this (for example, H, which belongs to every G). For in these cases too either the prior terms to which A belongs are unlimited or they come to a stop.

But in the case of terms that convert it is not the same way. For among terms that are counterpredicated there is none that is predicated in the primary way or finally; for all are in this respect, at least, similarly related to all, and if[43] the terms predicated are unlimited, the things we were puzzled about are unlimited in both directions—unless it is possible that they do not convert in the same way, but one as a coincident and the other as a predicate.[44]

42. I.e., are in direct contact, with no middle term.
43. Reading εἴτ'. . . ἐπ'.
44. The difference is explained at 83^a14–19.

1.20
Fixed Extremes and Unlimited Middles

It is clear that it is not possible for the intermediates to be unlimited if both the upward and the downward predications come to a stop. (By "upward" I mean the route toward what is more universal and by "downward" the one toward what is particular.) For if A is predicated of F, and the intermediates (the Bs) are unlimited, it is clear that it would be possible both for one thing to be predicated of another from A downward without limit—for before reaching F there would be unlimited middle terms—and also from F upward, before reaching A, unlimited ones. So if these are impossible, it is also impossible for there to be unlimited terms intermediate between A and F.

For even if someone were to say that some of ABF are contiguous to each other, so that there is nothing intermediate between them, while the others are impossible to take,[45] it makes no difference. For whichever of the Bs I take, the intermediates in the direction of A or of F will either be unlimited or not. Whichever one, then, is the first after which they are unlimited, whether immediate or non-immediate, makes no difference; for the ones after these are unlimited.

1.21
Privative Demonstrations Come to a Stop

It is evident too that a privative demonstration will come to a stop if indeed a positive one comes to a stop in both directions. For suppose that it is not possible either to go on upward without limit from the last (I call "last" the term that belongs to no other, **82b1** although another belongs to it—for example, F [above]), or to go on downward from the first to the last (I call "first" the term that is itself said of another, although no other is said of it). If this is so, it will come to a stop also in the case of negation.

For there are three ways that not belonging can be proved. For in one case B belongs to everything to which C does and A belongs to nothing to which B does. With regard to BC, then, and always in the case of the second interval, it is necessary to proceed toward immediates; for this interval is positive. As for the other term, it is clear that if it does not belong to anything prior, for example, D, this one will have to belong to every B. And if it, again, does not belong to anything else prior to D, that one will have to belong to every D. So, since the upward route comes to a stop, the route to A will also come to a stop, and there will be some first term to which it does not belong.

Again, if B belongs to every A and to no C, A will belong to no C. And again, if one must prove this, it is clear that it will be proved either in the way above, in this

45. Because they are unlimited.

way, or in the third way. The first way has been described, and the second will now be proved. If one proves in this way, for example, that D belongs to every B and to no C,[46] then it is necessary for something to belong to B. And if this, again, is not going to belong to C, [one must get that] something else does belong to D and does not belong to C. Since, then, belonging to something ever higher comes to a stop, not belonging will also come to a stop.

The third way that was mentioned is this: if A belongs to every B and C does not belong to B, C does not belong to everything to which A belongs. This, again, will be proved either in the ways described above or else in a similar way [to this one]. In the former ways, certainly, it comes to a stop, but if it is in the latter way, one will again get that B belongs to E, but C does not belong to every E. And so on in the same way. But since it was assumed that in the downward direction too it comes to a stop, it is clear that C's not belonging will also come to a stop.

It is evident that even if something is not proved by one route but by all of them—sometimes in the first figure, sometimes in the second or third, it will come to a stop even so. For the routes are limited, and limited things taken limited times are necessarily limited.

It is clear, then, that it comes to a stop in the case of privations, if indeed it does so in the case of belonging. That it does so in the latter case will be evident if we get a theoretical grasp on the issue logico-linguistically, as follows.

1.22
When Either Extreme Is Fixed, Affirmative Premises Must Be Limited

This is clear in the case of things predicated in the what-it-is; for if it is possible to define something, or if its essence is knowable, but it is not possible to go through an unlimited number of things, the things predicated in its what-it-is must be limited.

We argue universally as follows. It is indeed possible to say truly that a white thing is walking and that the large thing there is a log, and, again, that a log is large and a human is walking. But it is one thing to say the former and quite another to say the latter. For when I say that a white thing is a log, I say that something that is coincidentally white is a log, but not that the white thing is of the log as its underlying subject; for in fact it is not the case that, being white or precisely a sort of white, it came to be a log—so it is not a log, except coincidentally. But when I say that a log is white, I do not say that another thing is white and that that thing is coincidentally a log, as when I say that a musical thing is white (for then I am saying that a human, who is coincidentally musical, is white). Instead, the log is the underlying subject, which is precisely what came to be white, without being another thing than precisely a log or a sort of log. If,

46. Reading δεικνύῃ, restoring ὅτι, and omitting εἰ.

then, one must legislate, let speaking in the latter way be predicating, and speaking in the former either not predicating at all or else predicating not unconditionally but coincidentally. (What is predicated is like the white, what it is predicated of is like the log.)

Let it be assumed, then, that what is predicated is always predicated unconditionally, and not coincidentally, of what it is predicated of; for this is how demonstrations demonstrate. So when one thing is predicated of another, either it is in that thing's what-it-is or it says that the latter has some quality or quantity, or is relative [to something], or is doing something, or is being affected by something, or is somewhere, or somewhen.

Further, terms that signify substance signify precisely that thing of which they are predicated, or precisely that sort of thing. Those, on the other hand, that do not signify substance, but are said of some underlying subject that is neither precisely what that thing is nor precisely what sort of thing that thing is, are coincidents—for example, white is a coincident of a human. For the human is neither precisely white nor precisely a sort of white, but rather an animal, presumably; for a human is precisely an animal. But terms that do not signify substance must be predicated of some underlying subject, and there cannot be anything white that is not white by being some other thing. (For one must say goodbye to the Forms; for they are just noise, and if there are any, they are irrelevant to the account; for demonstrations are concerned with these other sorts of things.)

Further, if it is not possible for this to be a quality of that and that of this, that is, a quality of a quality, it is impossible for things to be counterpredicated of each other in this way. On the contrary, although it is possible to say something true, it is not possible to counterpredicate truly.

Otherwise, indeed, a term will be predicated as substance, that is, as kind or difference of what it is predicated of. But it has been proved that these terms will not be unlimited, either downward or upward. For example, neither [the upward series] human is two-footed, two-footed is animal, animal is something else, . . . ; nor [the downward series] animal [predicated] of human, human of Callias, and Callias of something else in the what-it-is. For every substance of this sort can be defined, but one cannot go through an unlimited number of things in thought. So they are not unlimited either upward or downward. For it is impossible to define a substance of which unlimitedly many things are predicated. Nor, on the other hand, will things be counterpredicated of each other as kinds; for then each would be precisely a sort of itself. Nor, indeed, can anything be predicated of a quality or the rest, unless it is predicated coincidentally; for these are all coincidents and are predicated of substances.

But then neither can they be unlimited in the upward direction; for something that signifies either a quality, or a quantity, or something of this sort, or else one of the things in the substance, is predicated of each of these. But the latter are limited, and the kinds of predicate are limited—either quality, quantity, relative, doing, being affected, where, or when.

It is assumed, then, that one thing is predicated of one thing, and that whatever things are not what something is are not predicated of themselves. For these are all coincidents (although some are intrinsic, while some belong in another way); and we say that all of them are predicated of an underlying subject, while what is coincident is not an underlying subject; for we posit nothing to be of this sort that is not said [to be] what it is said [to be] by being another thing; rather, it is itself predicated of another thing.[47]

Neither in the upward direction, therefore, nor in the downward one, will one thing be said to belong to one thing. For the coincidents are all said of things included in the substance of each thing, and these are not unlimited; and in the upward direction there are both these things and their coincidents, and neither of these is unlimited. Therefore, it is necessary for there to be something of which something is predicated in the primary way, and something else of this, and for this to come to a stop, and for there to be things that are no longer predicated of anything else that is prior and of which nothing else prior is predicated.

This is one way of demonstrating the claim, but there is yet another. If there is a demonstration of things that some prior thing is predicated of, and if for the things of which there is demonstration one cannot either be in a better condition in relation to them than by knowing them, or know them without a demonstration, and if one thing is known through others, and we neither know these others nor are in a better condition in relation to them than by knowing them, then we will not have scientific knowledge of what is known through them.

If, then, it is possible to know something unconditionally through demonstration, and neither from something else nor on the basis of a hypothesis, it is necessary for the intermediate predicates to come to a stop. For if they do not come to a stop and there is always something above whatever term has been taken, there will be a **84^a1** demonstration of all of them. So if it is not possible to go through unlimited things, we will not know through demonstration things of which there is a demonstration. If, then, we are not in a better condition in relation to them than by knowing them, it will not be possible to have scientific knowledge of anything through demonstration unconditionally, but only on the basis of a hypothesis.

From a logico-linguistic point of view, then, on the basis of these considerations, one might be persuaded of what we said; but from the point of view of analytics, the following considerations make it evident in a more concise way that predicates cannot be unlimited either upward or downward in the demonstrative sciences with which our investigation is concerned.

For demonstration has to do with what belongs intrinsically to things. But what is intrinsic is twofold; for it includes both the things that belong to something by being present in its what-it-is, and also the things in whose what-it-is that thing belongs. For example, the odd in relation to number: odd belongs to number and

47. Deleting καὶ τοῦτο καθ' ἑτέρου.

number itself is present in the account of it; and, again, magnitude and divisibility, which are present in the account of number. It is not possible for either of these to be unlimited—for example, as odd is related to number; for then there would again be something else belonging to odd in which odd was present; and if this is the case, number will be present in a primary way in what belongs to it. If, then, it is not possible for unlimitedly many things of this sort to belong in the [what-it-is of] one thing, they will not be unlimited in the upward direction either. But then, it is necessary for all of them, at any rate, to belong to the primary one, that is, to number, and number to them, so that they will convert and not exceed it. Nor, again, can those present in the what-it-is be unlimited; for then it would be impossible for it to be defined.

So if all the predicates are said of things intrinsically, and these are not unlimited, then the ones in the upward direction will come to a stop, and so in the downward direction too. And if this is so, the ones intermediate between two terms will also always be limited.

But if this is so, it is at the same time clear too that it is necessary for there to be starting-points of demonstrations, and that there cannot be demonstration of everything (which as we said at the start[48] is precisely what some people claim). For if there are starting-points, it is not the case that everything is demonstrable, nor is it possible to proceed without limit. For either of these being the case amounts to nothing other than there being no immediate and indivisible intervals, but all being divisible. For it is by inserting a term in between, and not by adding an additional one, that what has been demonstrated is demonstrated. So if it were possible for this to go on without limit, it would be possible for there to be unlimitedly many middle terms between two terms. But this is impossible if the predicates come to a stop in the upward and **84b1** downward directions. And that they do come to a stop we have proved from the logico-linguistic point of view earlier and from that of analytics just now.

1.23
Two Corollaries

Now that this has been proved, it is evident that if the same term belongs to two things (for example, A belongs to both C and D), neither of which is predicated of the other (either not at all or not in every case), then it will not always belong in virtue of something common. For example, having angles equal to two right angles belongs to isosceles and scalene in virtue of something common (for it belongs to them insofar as they are a certain sort of figure and not insofar as they are something else). But this is not always so. For let B be that in virtue of which A belongs to C and D. It is clear, therefore, that B too belongs to C and D in virtue of another thing that is common, and that thing in virtue of something else, so that unlimitedly

48. 72b6–7.

many terms would fall between two terms. But this is impossible. Therefore, it is not necessary for the same term always to belong to several things in virtue of something common, if indeed there are to be immediate intervals.

It is necessary, however, that the terms be in the same kind and come from the same immediate premises, if indeed the common thing is to be something belonging to them intrinsically; for, as we saw,[49] it is impossible for what is proved to cross from one kind to another.

It is evident too that when A belongs to B, if there is a middle term, it will be possible to prove that A belongs to B, and the elements of this proof are these[50] and are the same in number as the middle terms; for the immediate premises are the elements, either all of them or [just] the universal ones. But if there is no middle term, there is no demonstration; instead, this is the route to the starting-points.

Similarly, if A does not belong to B, if there is a middle, or rather a prior, term to which A does not belong, there is a demonstration, but if there is no such term, there is no demonstration, but rather a starting-point. And there are as many elements as terms; for the premises containing these terms are the starting-points of the demonstration. And just as there are some indemonstrable starting-points which say that this is this (that is, that this belongs to this), so too there are some that say that this is not this (that is, that this does not belong to this). So there will be starting-points saying that something is [the case] and others saying that something is not [the case].

When one has to prove something, one must assume what is predicated in the primary way of B. Let it be C; and of this let D be similarly predicated. If one always proceeds in this way, no outside premise or [term] not belonging to A will ever be assumed in the proof. Instead, the middle terms will always be thickened until they become indivisible and a unit. And when they become immediate, they are a unit, and the immediate premise is the premise that is unconditionally a unit. And just as in other areas, the starting-point is something simple, but this is not the same everywhere; instead, in weight it is the mina, in a melody it is the quarter-tone, and something else in something else. Likewise, in a deduction the unit is an immediate premise, and in demonstration and scientific knowledge it is understanding.

In deductions proving that something belongs, nothing falls outside, while in privative ones, it is in one case—that is, when the thing does not belong[51]—that nothing falls outside the thing. For example, suppose A does not belong to B through C (for suppose C belongs to every B and A to no C): if one next has to prove that A belongs to no C, one must assume a middle term between A and C; and one will always proceed like this.

49. 1.7.
50. Reading ταῦτα.
51. Reading μὴ ὑπάρχειν.

And if one has to prove that D does not belong to E, due to C belonging to every D and to no E, the middle term will never fall outside E (this is the term to which it must belong).

In the case of the third way, the middle term will never go outside either the term of which one must predicate a privation or the term one must predicate privatively.

1.24
The Superiority of Universal Demonstration

Some demonstrations are universal, others particular, and some are positive, others privative, and there is a dispute about which ones are better. It is the same way too concerning demonstrations that are called demonstrative and those by reducing to the impossible. First, then, let us investigate universal and particular demonstrations; and when we have made the issue clear there, let us speak about the ones that are called demonstrative and those by reducing to the impossible.

It might perhaps seem to some people, if they investigate in the following way, that particular demonstration is better. For if a demonstration by which we more know scientifically is a better demonstration (for this is a virtue characteristic of demonstration), and if we more know something scientifically when we know it intrinsically, rather than in virtue of something else (for example, we know musical Coriscus better when we know that Coriscus is musical than when we know that a human[52] is musical; and likewise in other cases), and if a universal demonstration proves that something else, and not the thing itself, is in fact such-and-such (for example, that the isosceles is in fact such-and-such, not because it is isosceles but because it is a triangle), while a particular one proves that the thing itself is in fact such-and-such—if, then, intrinsic demonstration is better, and if particular demonstration rather than universal demonstration is of this sort, particular demonstration will also be better.

Further, if the universal is not something beyond the particulars; and if a demonstration produces a belief that the thing with regard to which it demonstrates is something, that is, that it is a sort of nature belonging among the things that there are (for example, a nature of a triangle beyond the particular sorts, that of a shape beyond the particular sorts, and that of a number beyond the particular sorts); and if a demonstration is better when it concerns something that is rather than something that is not; and one through which we will not be deceived is better than one through which we will be deceived; and if the universal demonstration is of this latter sort (for, as they proceed, they prove things as they do in the case of proportion, for example, that whatever is of such-and-such a sort—neither line nor number nor solid nor

52. Reading ἄνθρωπος.

plane, but something beyond these—will be proportional)—if, then, it is universal demonstration that is more like this, and if it is less concerned with what is than is **85^{b}1** particular demonstration, and if it produces a false belief, universal demonstration will be worse than particular demonstration.

Or rather, first, does the other argument not apply any more to universal demonstration than to particular demonstration? For if having angles equal to two right angles belongs to something not insofar as it is isosceles but insofar as it is a 5 triangle, someone who knows that an isosceles has angles equal to two right angles knows it less, insofar as it is itself, than someone who knows that a triangle does. And, in general, if it is not insofar as it is a triangle that [having angles equal to two right angles] belongs to it, and then one proves it to belong, it will not be a demonstration. But if this is the case, the one who knows each thing insofar as it belongs knows better. If, then, triangle extends further than isosceles, and the account is the same (that is, if triangle is not said of things homonymously), and if having 10 angles equal to two right angles belongs to every triangle, then it is not the triangle insofar as it is isosceles but rather the isosceles insofar as it is a triangle that has such angles. So someone who knows universally knows it more insofar as it belongs than someone who knows particularly. Therefore, the universal demonstration is better than the particular one.

Further, if the universal [is defined by] a single account, and not a homonymy), it 15 will be no less than some of the particulars, but actually more so, inasmuch as what is incapable of passing away is found among universals, while the particulars are capable rather of passing away. Further, there is no necessity to suppose that the universal is something beyond these, on the grounds that it indicates one thing, any more than in the case of the other things that signify not a what [something is] but either a 20 quality, a quantity, a relative, or a doing. Therefore, if this is supposed, it is not the demonstration but the listener that is the cause.

Further, if demonstration is probative deduction of a cause and the why, and the universal is more of a cause (for that to which something belongs intrinsically is itself the cause of this belonging; but the universal is primary; therefore, the universal is 25 the cause), the result is that the [universal] demonstration is also better; for it is more of the cause and the why.

Further, we seek the why up to a certain point, and we think we know something when it is not the case that it is because of something else that it comes about or is; for the last term is in fact an end or limit in this way. For example, for the sake of what did he come? In order to get the money, and this in order to pay back what he 30 owed, and this in order not to act unjustly. And proceeding in this way, when it is no longer because of something else or for the sake of something else, we say that it is because of this as end that he came (or that the state of affairs is or comes about), and that then we most of all know why he came. If, then, the same holds in the case of all causes and all whys, and if in the case of causes for-the-sake-of-which we most 35 of all know in this way, in the other cases too we most of all know when the thing in

question no longer belongs because of something else. When, then, we know that the exterior angles are equal to four right angles because it is isosceles, it still remains to
86ᵃ1 ask why the isosceles is so: because it is a triangle, and this because it is a rectilinear figure. And if this is no longer so because of something else, it is then that we most of all know. And it is then too that our knowledge is universal. Therefore, the universal demonstration is better.

Further, the more particular a demonstration is, the more it falls within the province of the unlimited, while universal demonstration falls within the province of the
5 simple and the limit. But insofar as things are unlimited, they are not scientifically knowable, while insofar as they are limited, they are scientifically knowable. Therefore, they are more scientifically knowable insofar as they are universal than insofar as they are particular. Therefore, universals are more demonstrable. And of things that are more demonstrable there is more of a demonstration (for correlatives increase concomitantly). Therefore, the universal demonstration is better since it is more of a demonstration.

10 Further, if a demonstration in virtue of which one knows both this and something else is more choiceworthy than one in virtue of which one knows this alone, and if someone who possesses a universal demonstration knows the particular thing too, while the latter does not know the universal one,[53] the result is that in this way too universal demonstration will be more choiceworthy.

Further, also in the following way. For proving a universal is more a matter of proving through a middle term that is nearer the starting-point. And the immediate
15 is nearest; indeed, it is a starting-point. If, then, a demonstration that proceeds from a starting-point is more exact than one that does not proceed from a starting-point, a demonstration that proceeds more from a starting-point is more exact than one that does so less. But the universal demonstration is more like this. Therefore, [the more] universal demonstration will be better. For example, if one had to demonstrate that A belongs to D, with B and C as middle terms, B being higher: the result is that a
20 demonstration through B is more universal.

Though some of the points we have made are logico-linguistic, it is above all clear that the universal demonstration has the most control, because in getting hold of a premise that is prior we also in a way know the one that is posterior to it, that is, we get hold of it potentially. For example, if one knows that every triangle has angles
25 equal to two right angles, one in a way also knows of the isosceles that it has angles equal to two right angles; one knows it potentially, even if one does not know of the isosceles that it is a triangle. But one who gets hold of the latter premise does not in any way know the universal, neither potentially nor actually.

30 Also, the universal is intelligible, while the particular ends up in perception.

53. Reading τὸ καθόλου.

1.25
Superiority of Probative Demonstration

Let us say this much, then, about why universal demonstration is better than particular demonstration. That probative demonstration is better than privative demonstration will be clear from what follows.

For let a better demonstration, other things being equal, be one that proceeds from fewer postulates, hypotheses, or premises. For if these are equally known, knowledge will accrue more quickly in this way, and this is more choiceworthy.

The argument for the proposition that a demonstration proceeding from fewer things is better is, generally speaking, as follows. For if the middle terms are taken to be equally known, and the prior terms better known, let one demonstration be that A belongs to E through the middle terms B, C, and D, and let the other demonstration be that A belongs to E through F and G. Then that A belongs to E and that A belongs to D are on the same level. But that A belongs to D is prior to and better known than that A belongs to E; for the latter is demonstrated through the former; and that through which something is demonstrated is the more persuasive of the two. Therefore, a demonstration through fewer things is also better, other things being equal.

Both probative demonstration and privative demonstration are proved through three terms and two premises, but the one assumes that something is the case, while the other assumes both that something is the case and that something is not the case. Therefore, the latter proceeds through more things,[54] and so is worse.

Further, since it has been proved[55] that it is impossible for a deduction to be produced when both premises are privative, and that it must be that [only] one premise is privative while the other says that something belongs, in addition to the former one must get the latter. For as a demonstration increases,[56] it is necessary for the positive premises to become more numerous, while it is impossible for there to be more than one privative premise in any deduction. For let A belong to no B and B belong to every C. If one must next increase both premises, one must put in a middle term. Let it be D between A and B and E between B and C. It is evident that E is positive, while D is said positively of B, but in relation to A is posited as privative. For D is predicated of every B, and A must belong to no D. There is, then, [only] one privative premise, AD.

It is the same way too in the case of the other deductions. For the middle term for the positive terms is always affirmative in both directions, while in the case of the privative terms, it is necessary for it to be privative in one of the two, so that [only] one premise of this sort is produced, the others being positive.

54. Since it involves negation.
55. *APr.* 1.4–6, $41^{b}6$–7.
56. $78^{a}14$–21.

If, then, that through which something is proved is the better known and more persuasive of the two, and if privative demonstration is proved through positive demonstration while the latter is not proved through the former, positive demonstration, being prior, better known, and more persuasive, will be better.

Further, if the universal immediate premise is a starting-point of deduction, and if the universal premise is affirmative in probative demonstration and negative in privative demonstration, and if an affirmative premise is prior to and better known than a negative one (for it is through the affirmation that the negation is known, and the affirmation is prior, just as being is prior to not being), the result is that the starting-point of probative demonstration is better than that of privative demonstration, and a demonstration that makes use of better starting-points is better.

Further, they are more like starting-points; for without a probative demonstration there is no privative demonstration.

1.26
Superiority of Direct Demonstration

87a1 Since positive demonstration is better than privative demonstration, it is clear that it is also better than demonstration by reducing to the impossible. But one must know what the difference is between them.

Let, then, A belong to no B and B to every C. It is necessary, then, that A belong to no C. If the assumptions are made in this way, the privative demonstration that A does not belong to C will be probative. But the demonstration by reducing to the impossible goes this way: if one must prove that A does not belong to B, one must assume that it does belong, and that B belongs to C, so that it follows that A belongs to C. But let it be known and agreed that this is impossible. Therefore, it is not possible for A to belong to B. If, then, it is agreed that B belongs to C, it is impossible for A to belong to B.

The terms, then, are ordered in the same way, but which privative premise is more known makes a difference—that A does not belong to B or that A does not belong to C. When the conclusion (that it is not the case) is more known, a demonstration by reducing to the impossible comes about; when the premise inside the deduction is more known, a demonstrative proof does. For by nature the AB premise is prior to the AC premise, for the premises from which the conclusion is deduced are prior to the conclusion. For that A does not belong to C is a conclusion, while that A does not belong to B is something from which the conclusion is deduced. For if something happens to be denied, it does not follow that this is a conclusion and the others the premises from which it was deduced; on the contrary, the premises of a deduction stand in the relation of whole to part or of part to whole, but the AC and BC premises are not related to each other in this way.

If, then, a demonstration that proceeds from what is more known and prior is better, and if in both these sorts of demonstration[57] conviction proceeds from something not being the case, but in the one from something prior and in the other from something posterior, a privative demonstration will be unconditionally better than a demonstration by reducing to the impossible. So too positive demonstration, which is better than privative demonstration, will also be better than demonstration by reducing to the impossible.

1.27
The Relative Exactness of Sciences

One science is more exact than another, and prior to it, if it is both of the that and the why, and not of the that separately from the why; and if it does not have an underlying subject, while the other does have an underlying subject (as, for example, arithmetic is more exact than harmonics); and if it makes fewer assumptions, while the other depends on some additional assumption (for example, arithmetic is more exact than geometry). By "an additional assumption" I mean, for example, that a unit is a substance that does not have a position and a point is a substance that has a position—the latter depends on an additional assumption.

1.28
The Unity of a Science

A science is one when it is of one kind—of whatever things are composed of the primary things and are intrinsically parts or affections of these. One science is distinct from another when their starting-points are neither composed of the same things nor are those of the one composed of those of the other. There is a sign of this when one arrives at the indemonstrables. For they must be the same in kind as the things demonstrated. And there is also a sign of this when the things proved through these are in the same kind, that is, are homogenous.

1.29
Multiple Demonstrations of the Same Thing

It is possible for there to be several demonstrations of the same thing, not only when one takes non-continuous middle terms from the same column (for example, C, D, and F for AB), but also when the columns are distinct. For example, let A be

57. I.e., the privative one and the one by reducing to the impossible.

changing, D being moved, B being pleased, and then G coming to rest. It is true, then, to predicate D of B and A of D; for anyone who is being pleased is being moved and what is being moved is changing. Again, it is true to predicate A of G and G of B; for everyone who is being pleased is coming to rest[58] and one who is coming to rest is changing. So the deductions proceed through distinct middle terms that do not come from the same column. (It is not, though, that neither of the middle terms is said of the other; for it is necessary for both to belong to one and the same thing.)

One must also investigate in how many ways it is possible to produce a deduction of the same thing in the other figures.

1.30
No Demonstration of What Happens by Luck

Of what happens by luck, there is no scientific knowledge through demonstration. For what happens by luck is neither necessary nor for the most part, but is rather something that comes about outside these; but demonstration is of one or the other of these. For every demonstration proceeds either through premises that are necessary or through premises that hold for the most part. And if the premises are necessary, the conclusion is necessary too, but if they hold for the most part, so too does the conclusion. So if what happens by luck is neither necessary nor for the most part, there will be no demonstration of it.

1.31
No Demonstration through Perception

Nor is it possible to have scientific knowledge through perception. For even if perception is of a such-and-such and not of a this something, what you perceive, at any rate, is necessarily a this something that is in a place and at a time. But it is impossible to perceive what is universal and holds in every case; for no universal is a this [something] or at a particular time; for otherwise it would not be universal; for it is what is always and everywhere that we say is universal.

Since, then, demonstrations are universal, and universals cannot be perceived, it is evident that it is not possible to have scientific knowledge through perception either. On the contrary, it is clear that even if it were possible to perceive that a triangle has angles equal to two right angles, we would seek a demonstration of it and would not,

58. *Rh*. 1369ᵇ33–35.

as some people say,[59] have scientific knowledge of it; for, necessarily, what we perceive are particulars, while scientific knowledge is to know the universals.

That is why, if we were on the moon and saw the earth interposed, we would not know the cause of the eclipse. For we would perceive that it is now eclipsed but not at all why. For the perception was not of the universal. Nonetheless, if we observed this happening often, after having hunted down the universal, we would have a demonstration; for it is from many particulars that the universal becomes clear.

But the universal is estimable because it makes clear the cause. So, where the cause of things is distinct from the things themselves, universal demonstration is more estimable than perceptions or understanding. Concerning the primary things, though, another account [is needed].

It is evident, then, that by perceiving it is impossible to have scientific knowledge of anything demonstrable—unless one calls perceiving just this: to have scientific knowledge through demonstration.

Nonetheless, some of our problems can be traced back to a want of perception. For in some cases if we saw we would not inquire—not because we know by seeing but because we grasp the universal from seeing. For example, if we saw the crystalline stone with a hole in it and the light passing through it, it would also be clear why—when it is also the case that because of seeing[60] it separately in a given case, we at once understand that it is like this in every case.

1.32
Not All Deductions Can Have the Same Starting-Points

It is impossible for all deductions to have the same starting-points. First, let us get a theoretical grasp on this logico-linguistically.

In fact, some deductions are true and some false. For even if it is possible to deduce a truth from falsehoods, this comes about only once—for example, if A is true of C but B, the middle term, is false, for then A does not belong to B nor B to C. But if middle terms are assumed for these premises, they will be false, because every false conclusion is deduced from falsehoods, while true conclusions are deduced from truths. But falsehoods and truths are distinct.

Next, not even falsehoods are deduced from the same things as each other; for there are falsehoods that are contrary to each other and cannot be the case at the same time—for example, that justice is injustice or cowardice, that a human being is a horse or cow, or that what is equal to something is greater or less than it.

On the basis of what has been established, on the other hand, [we get our theoretical grasp] as follows; for not even all truths have the same starting-points. For

59. E.g., Protagoras, who equates knowledge with perception.
60. Reading καὶ εἰ διὰ τό.

the starting-points of many of them are distinct in kind and do not apply to each other—for example, [those that apply] to units do not apply to points; for units do not have position while points do have it. But it is necessary, at any rate, [for any that do apply] to apply either to middle terms (either from above or from below) or to have some terms placed inside or to some outside.[61]

But it is not possible, either, for there to be some common starting-points from which everything will be proved (by "common starting-points," I mean, for example, that everything must be affirmed or denied). For the kinds of the beings are distinct, and some things belong to quantities alone and others to qualities alone, and it is with the help of these that a proof is given through the common things.

Further, the starting-points are not much fewer than the conclusions; for the premises are starting-points, and the premises involve either adding a term or inserting one in between.[62]

Further, the conclusions are unlimited, the terms limited.

Further, some starting-points are necessary, others contingent.

When we investigate in this way, it is impossible for the starting-points to be the same and limited if the conclusions are unlimited. But if someone took the claim[63] in another way, saying, for example, that these ones here are the starting-points of geometry, these ones here of [arithmetic] calculation, these ones here of medicine, what else would he be saying except that sciences have starting-points? But it is ridiculous to say that the starting-points are the same because they are the same as themselves; for in that way everything turns out to be the same.

Neither does the claim that anything whatsoever is to be proved from all things amount to seeking the same starting-points for all things; for this is too simple-minded. For this is not what happens in the mathematical sciences that are evident, nor is it possible on analysis; for the immediate premises are starting-points, and a different conclusion is reached when an additional immediate premise is added. And if someone were to say that the primary immediate premises are the ones that are starting-points, there is one in each kind.

But if the claim is neither that everything must be proved from all the starting-points nor that they are distinct in that there are different ones for each science, it remains that the starting-points of all things are in the same kind even though these [conclusions] proceed from those [starting-points], and those from these other ones. But it is evident that this is not possible either; for it has been proved that the starting-points of things that are different in kind are themselves different in kind. For starting-points are of two sorts, those from which and those about which; and while the former are common, the latter are special—for example, number and magnitude.

61. 78b13, 87a16.

62. 84a36.

63. I.e., that all deductions have the same starting-points.

1.33
Scientific Knowledge and Belief

What is scientifically knowable and scientific knowledge are different from what is believable and belief; that is because scientific knowledge is universal and through necessities, and what is necessary does not admit of being otherwise. But there are some things that are true and are the case, although they also admit of being otherwise. It is clear, then, that concerning these things there is no scientific knowledge; for otherwise what admits of being otherwise would not admit of being otherwise. But then neither is there understanding (for by "understanding" I mean a starting-point of scientific knowledge), that is, non-demonstrative scientific knowledge; and this is the supposition of an immediate premise. But understanding, scientific knowledge, and belief are true, and so is what is said to come through them. So it remains for belief to be concerned with what is true or false but admits of being otherwise. And this is the supposition of a premise that is immediate[64] and not necessary.

And this agrees with what appears to be so; for belief is unstable, and so is the nature [it is concerned with]. In addition, no one thinks that he believes something when he thinks that it does not admit of being otherwise, but rather that he has scientific knowledge of it. On the other hand, when he thinks that something is so but that nothing prevents it from being otherwise, then he thinks that he believes, on the supposition that belief applies to this sort of thing but scientific knowledge to what is necessary.

How, then, is it possible to believe and have scientific knowledge of the same thing, and why is belief not scientific knowledge, if one posits that everything one knows it is possible to believe? For the knower and the believer will follow the same path through the middle terms until they come to the immediates, so that if indeed the former knows, the believer knows too. For just as it is possible to believe the that, it is also possible to believe the why, and this is the middle term.

Or if one supposes what does not admit of being otherwise in the way one possesses[65] the definitions through which demonstrations proceed, will one then not believe but have scientific knowledge? But if one supposes them to be true but not that the things in question belong in virtue of the substance and in virtue of the form, will one then believe and not truly have scientific knowledge? Will one believe both the that and the why if one's believing has come through intermediates, and only the that if it has not come through intermediates?

But there cannot be belief and scientific knowledge about the same thing in every way. Instead, just as in a certain way there can be both false and true belief about the same thing, so there can be both scientific knowledge and belief about the same thing. For in fact if there is true and false belief about the same thing in the way

64. Perhaps simply meaning "not demonstrated" in this instance.
65. Reading ἔχει.

some people say, it follows that one is committed to absurdities, in particular, that one does not believe what one falsely believes. But since things are said to be the same in several ways, in one way it is possible and in another way it is not. For to
30 believe truly that the diagonal is commensurable is absurd. But because the diagonal with which the beliefs are concerned is the same, in this way they are about the same thing—although the essence of each that is in accord with the account is not the same. In the same way, there is both scientific knowledge and belief about the same thing. For the former is about an animal in such a way that it does not admit of not being an animal, the latter in such a way that it does admit of it—for example, if the
35 former is about what is precisely a human being and the latter about a human being but not what is precisely a human being. The thing is the same because it is a human being, but the way [they are about it] is not the same.

It is evident from these considerations that it is not possible to believe and to have scientific knowledge about the same thing at the same time. (For then one would at the same time have a supposition that the same thing admits of being otherwise
89b1 and does not admit of being otherwise. And this is precisely what is not possible.) In distinct people it is possible for there to be each of these about the same thing, as was said. But in the same person it is not possible even in this way. For he would at the same time have a supposition, for example, that a human being is precisely an animal (for this, we saw, is what it is for it not to be possible for a human being not to be an
5 animal) and also not precisely an animal (for let this be what it is for it to be possible).

As for how to distribute the remaining [objects of cognition] among thought, understanding, scientific knowledge, craft knowledge, practical wisdom, and theoretical wisdom—this is rather a matter in part for natural science and in part for the theoretical investigation of ethics.[66]

1.34
Acumen

10 Acumen is a sort of good guesswork that hits on the middle term in an imperceptible amount of time. For example, if someone sees that the moon always has its bright side toward the sun and quickly understands why this is so (because it gets its light from the sun); or knows why someone is speaking to a rich person (because he is borrowing money); or why people are friends (because they are enemies of the same person). For on seeing the extremes, one gets knowledge of all the causes, the middle
15 terms. A is having its bright side toward the sun; B is getting light from the sun; C is the moon. B (getting light from the sun) belongs to C (the moon); and A (having its bright side toward that from which it gets its light) belongs to B, so that A belongs
20 to C through B.

66. *DA* 3.4–7, *NE* 6.3–8.

BOOK 2

2.1
The Four Scientific Questions

The things we inquire about are equal in number to the things we have scientific knowledge of. And we inquire about four things: the that, the why, whether something is, what something is. For when we inquire as to whether this or that is the case, positing a number of terms (for example, whether the sun is eclipsed or not), we are inquiring about the that. A sign of this is that, on finding that it is eclipsed, we stop; and if from the start we know that it is eclipsed, we do not inquire about whether it is. But when we know the that, we inquire about the why—for example, when we know that it is eclipsed or that the earth moves, we inquire about why it is eclipsed or why it moves.

These, then, we inquire about this way. But some things we inquire about in another way—for example, whether there is or is not a centaur or a god. (I mean whether there is unconditionally one or not, not whether it is white or not.) And when we have come to know that it is, we inquire about what it is—for example, what, then, is a god? or what is a human being?

2.2
The Search for a Middle Term

These, then, are the things we inquire about and which—when we have discovered them—we know, and this is how many they are. And when we are inquiring about the that or whether something is unconditionally, we are inquiring about whether or not there is a middle term for it; and when, having come to know either the that or whether the thing is (whether partially or unconditionally), we inquire in turn about the why or the what-it-is, we are then inquiring about what the middle term is. (Partially or unconditionally: I mean by "partially" is the moon eclipsed? or is it **90^a1** waxing? For in such cases we are inquiring about whether it is or is not something. By "unconditionally" I mean whether there is or there is not a moon or night.)

It follows, therefore, that in all our inquiries we are inquiring either about whether there is a middle term or what the middle term is. For the middle term is the cause, and in all cases it is the cause that is being inquired about. Is it eclipsed? Is there some cause or not? After that, having come to know that there is one, we inquire about what it is. For the cause of a substance being not this or that but being unconditionally, or of its being not unconditionally but rather being one of the things that belong to it intrinsically or coincidentally—this is the middle term. (By "what is unconditionally" I mean the underlying subject—for example, the moon, earth, sun,

or triangle; and by "one of the things that belong to it" I mean the eclipse, equality, inequality, whether it is in the middle or not.)

For in all these cases it is evident that what it is and why it is are the same. What is an eclipse? A lack of light from the moon due to the earth's interposition. Why is there an eclipse? Or why is the moon eclipsed? Because the light leaves when the earth is interposed. What is a harmony? A numerical ratio between the high and the low. Why does the high harmonize with the low? Because a numerical ratio holds between the high and the low. Does the high harmonize with the low? Is there a numerical ratio between them? Having grasped that there is, [we ask] what then is the ratio?

That the inquiry is about the middle term is made clear by those cases in which the middle term is perceptible. For we inquire about it when we have not perceived it—for example, for the eclipse, we inquire about whether there is a middle term or not. But if we were on the moon, we would inquire neither about whether an eclipse comes about nor why it does; instead, these things would be clear at the same time. For from having perceived we would also come to know the universal. For the perception is that now [the earth] is interposed (for it is in fact clear that now there is an eclipse); and from this the universal would come about.

As we say, then, to know what it is is the same as to know why it is, and this either unconditionally and not regarding one of the things that belong to it, or regarding one of the things that belong to it—for example, that it has angles equal to two right angles, or it is greater or smaller.

2.3
Relations between Definitions and Demonstrations

It is clear, then, that inquiry with respect to all objects of inquiry is about a middle term. But we must now state how the what-it-is is proved, and in what way one can effect this reduction, and what a definition is, and of what, after first going through the puzzles concerning these things. Let us take as a starting-point for the arguments we are going to give the precise one that is most appropriate for those that have
90b1 preceded. For one might raise a puzzle as to whether one can know the same thing in the same respect both by a definition and by a demonstration, or whether this is impossible.

For a definition seems to be of the what-it-is, and the what-it-is in every case is universal and positive, while some deductions are privative and some are not universal—for example, those in the second figure are all privative and those in the third are not universal.

Next, not even of all the positive deductions in the first figure is there a definition—for example, that every triangle has angles equal to two right angles. The argument for this is that to have scientific knowledge of what is demonstrable is to possess the demonstration. So, since there are demonstrations of such things, it is

clear that there will not also be a definition of them. For otherwise one could have scientific knowledge through the definition without possessing the demonstration; for nothing prevents one from not having the two together.

Adequate assurance of this is to be had from induction too. For we have never yet come to know anything—neither anything belonging intrinsically nor anything belonging coincidentally—by defining it.

Further, if a definition provides knowledge of some substance, it is evident that things of this sort[67] are not substances.

It is clear, then, that there is not a definition of everything of which there is a demonstration. On the other hand,[68] is there a demonstration in every case of what there is a definition of, or not? There is one argument in this case too that is the same as before. For there is one science of one thing insofar as it is one. So, if indeed to have scientific knowledge of what is demonstrable is to possess a demonstration of it, something impossible will follow; for the one who possesses the definition of something without the demonstration will scientifically know [something demonstrable].

Further, the starting-points of demonstrations are definitions of which, as was proved previously,[69] there will not be demonstrations—either the starting-points will be demonstrable, and there will be starting-points of starting-points, and this will go on without limit, or else the primary things will be indemonstrable definitions.

But if there is not definition and demonstration of the same thing in every case, are they of the same one in some cases? Or is this impossible? For there is no demonstration of what there is a definition of. For definition is of the what-it-is, that is, of the substance; but all demonstrations, it is evident, hypothesize and assume the what-it-is—for example, mathematical demonstrations assume what a unit is and what odd is; and similarly for the other demonstrations.

Further, every demonstration proves something of something, that is, that it is or is not. But in a definition nothing is predicated of anything else—for example, neither animal of two-footed nor this of animal, nor indeed figure of plane; for plane is not figure nor is figure plane.

Further, proving what something is is different from proving that it is. A definition, then, makes clear the what-it-is, while a demonstration makes clear whether this is or is not predicated of that. And for a distinct thing there is a distinct demonstration, unless the demonstrations are related as part to whole. I mean by this that the isosceles has been proved to have angles equal to two right angles if every triangle has been proved to do so; for one is a part, the other a whole. But these things—that something is and what it is—are not related to each other in this way; for neither is part of the other.

67. I.e., things (affections) that belong intrinsically or coincidentally.
68. Reading τί δ'.
69. $72^{b}18$–25, $84^{a}29$–$^{b}2$.

It is evident, therefore, that there is not a demonstration of everything of which there is a definition, nor a definition of everything of which there is a demonstration, nor, in general, is it possible to have both of the same thing. So it is clear that definition and demonstration are not the same, nor is one included in the other; for then the underlying subjects would be similarly related.

2.4
Proving a Definition

Let us take it, then, that we have gone through these puzzles up to this point. But is there deduction and demonstration of the what-it-is, or is there not, as the argument just now hypothesized? For deduction proves something of something through a middle term. But what something is is special to it and is predicated in the what-it-is. And these terms necessarily convert. For if A is special to C, it is clear that it is also special to B and B to C, so that all are special to each other. But then if A belongs to every B in the what-it-is, and B is said universally of every C in the what-it-is, it is also necessary for A to be said of C in the what-it-is. But if one does not assume the premises by doubling in this way, it will not be necessary for A to be predicated of C in the what-it-is (if A is predicated of B in the what-it-is, but B is not in the what-it-is of everything it is predicated of). Both these premises, then,[70] will contain the what-it-is. Therefore, B too will be predicated of C in the what-it-is. If, then, both contain the what-it-is, that is, the essence, the essence will be found beforehand in the middle term. And, in general, if it is possible to prove what a human being is: Let C be human being, A the what-it-is, whether two-footed animal or some other thing. Therefore, if this is going to be deduced, it is necessary for A to be predicated of every B, and there will be a middle account other than A,[71] so that this too will be what a human being is. One assumes, then, what one ought to be proving—for B will also be what a human being is.

We must look at the issue in the case of the two premises, and the things that are primary and immediate; for then what we are saying becomes most evident. Those people, then, who try to prove through conversion what the soul is (or what a human being, or any other being, is) postulate it at the start—for example, if someone[72] were to claim that the soul is what is the cause of its own being alive, and that this is a self-moving number. For it is necessary to postulate that the soul is precisely a number that moves itself, in such a way as to be the same thing as it. For it is not the case
91b1 that if A follows B and B follows C, A will be the essence of C. Instead, it is[73] true to say only that A will be said of C—even if A is precisely some B and A is predicated of

70. Reading δὴ.
71. Reading τούτου. I.e., an account or definition of the essence.
72. E.g., Xenocrates.
73. Reading ἦν.

every B (for it is true that every case of being for a human is being for an animal, just as every human is an animal), but not in such a way that they are one thing.

If, then, one does not assume the premises in this way, one will not deduce that A is the essence of C, that is, its substance. But if you do assume them in this way, one will already have assumed beforehand what the essence of C is: B.[74] So one will not have demonstrated it; for one has assumed it at the start.

2.5
Definition and Division

But then neither does the route through divisions deduce [definitions], as was said in the analysis of the figures.[75] For it nowhere becomes necessary for the thing at issue to be the case because those things are the case, just as someone who does an induction does not demonstrate anything. For the conclusion must not be made into a question,[76] nor be the case due to being granted, but must be necessarily the case if those things are, even if the answerer denies it.

Is a human being an animal or is he inanimate? If[77] one assumed he is an animal, one has not deduced it. Next, every animal is either terrestrial or aquatic; one assumed that he is terrestrial. And that a human being is the whole—a terrestrial animal—is not necessary from what has been said, but one assumes this too. And it makes no difference whether one does this in many steps or in few; for it is the same thing. For those who proceed in this way actually make non-deductive use even of what can be deduced. For what prevents the totality of this from being true of a human being, and yet failing to make clear either the what-it-is or the essence of a human being? Further, what prevents one from adding something, subtracting something, or overlooking something in the essence?

Though these points are disregarded, it is possible to resolve the puzzles by assuming everything in the what-it-is, making the division successive by postulating what is primary, and omitting nothing. (And, this is necessary if everything falls into the division and nothing is omitted; for this is already indivisible.)[78] But nonetheless there is no deduction [of the definition] here;[79] on the contrary, if indeed it produces knowledge, it does so in another way. And this is nothing strange; for someone who does an induction, presumably, does not deduce anything either, but nonetheless makes something clear. But one who states the definition on the basis of the division does not give a deduction. For just as in the case of conclusions without middle

74. Reading τὸ B.
75. 1.31.
76. *Top*. 158ᵃ7–13.
77. Reading εἴτ'.
78. Perhaps an interpolation. 97ᵃ35–ᵇ6 explains the reasoning.
79. Reading ἔνεστι.

terms, if someone says that since these things are the case, it is necessary for this to be, it is possible to ask why, so it is too in the case of definitions by division. What is
92^a1 a human being? An animal that is mortal, footed, two-footed, wingless. Why? [one can ask] at each added posit. He will say, and prove by division (as he thinks), that everything is either mortal or immortal. But an account of this sort, taken as a whole, is not a definition, so that even if it were demonstrated by division, that certainly does
5 not make the definition into a deduction.

2.6
Other Failed Attempts to Deduce a Definition

But then is it even possible to demonstrate the what-it-is in accord with the substance, although on the basis of a hypothesis which assumes that the essence is the special composition of the things in the what-it-is, and that these alone are in the what-it-is, and that their totality is special to the thing? For this is the being for that thing. Or has one again assumed the essence in this case too? For it is necessary to
10 prove it through the middle term.

Further, just as in a deduction one does not assume what deduction is (for the premise from which the deduction proceeds is always a whole or a part[80]), so too the essence must not be present in the deduction, but must be separate from the assumptions. And one should meet the person who disputes that something has been
15 deduced by saying that "this is what a deduction is,"[81] and one should meet the person who says that the essence has not been deduced, by saying that "yes it has; for this is what we have been assuming the essence is." So it is necessary for something to be deduced without assuming what a deduction is or what an essence is.

The same holds if one wishes to prove it on the basis of a hypothesis—for example,
20 if what is being for the bad is what is being for the divisible, and if what is being for the contrary is what is being contrary to its contrary (in those cases where there is a contrary) and if the good is contrary to the bad, and the indivisible to the divisible, then what is being for the good is what is being for the indivisible. For here too one proves by assuming the essence and assumes it in order to prove the essence. "A
25 distinct one, however." Let it be so; for in demonstrations too one assumes that this is true of that; but not the same as it, nor something that has the same account as it and converts with it.

And both deductions—the one proving by division and the deduction proceeding in the foregoing way—face the same puzzle: Why will a human being be a two-footed terrestrial animal, and not an animal and terrestrial and a two-footed
30 thing?[82] For from the assumptions it is not necessary that what is predicated be one

80. 87^a22–23.
81. *Top*. 100^a25–27.
82. Retaining καὶ δίπουν.

thing; instead, it could be in the way in which the same human being is musical and knows grammar.

2.7
Proving Definitions

How, then, will a definer prove the substance or the essence? For he will not, as when demonstrating, make it clear from things agreed to be the case, that necessarily if they are the case, then something else is the case (for this is demonstration), nor will he, like someone who does an induction, make it clear—through the fact that the particulars are clear—that a totality[83] is a certain way, due to nothing being otherwise (for an induction does not prove what something is, but rather that it is or is not). And what other way remains? For of course one will not prove it by perception or by **92^{b}1** pointing one's finger.

Further, how then will one prove the what-it-is? For it is necessary for a person who knows what a human being or anything else is also to know that it is (for no one knows what the non-being is; on the contrary, one knows what the account or the name signifies when I say "goat-stag," but it is impossible to know what a goat-stag is). But then if one is to prove what something is and that it is, how will one prove them by the same argument? For the definition makes [only] one thing clear and so does the demonstration; but what a human being is and that a human being is are different things.

Next, we say that it is necessary for everything to be proved through a demonstration of what it is, unless it is its substance. But being is not the substance of anything; for being is not a kind. Therefore, there will be a demonstration that it is. And this, as things stand, is precisely what the sciences in fact do. For what a triangle signifies, this is what the geometer assumes, but that there is one, he proves. What, then, will a definer prove? What a triangle is? Therefore, knowing what a triangle is, he will not know that it is. But this is impossible.

It is also evident that in accord with the present modes of definition, definers do not prove that anything is. For even if there is something equidistant from the center, why is what has been defined that thing? And why is this a circle? For one could also say that it is mountain-copper.[84] For definitions do not make clear in addition [to the what-it-is] either that what they state is possible or that the definitions are of what they say they are of—on the contrary, it is always possible to ask "why?"

Therefore, if a definer gives a proof either of what something is or of what its name signifies, and it is never of the what-it-is, a definition will be an account that signifies the same thing as a name. But this is absurd. For, first, there will be definitions both

83. $92^{a}9$.
84. When, for example, the circle is composed of this.

of non-substances and of non-beings; for it is possible to signify even non-beings.
30 Further, all accounts will be definitions; for a name can be assigned to any account whatsoever, so that we will all talk in definitions and the *Iliad* will be a definition. Further, no demonstration would demonstrate that this name makes this thing clear; therefore, neither would definitions make this clear in addition [to the what-it-is].
35 From these considerations it appears that definition and deduction are not the same either, and that there cannot be a deduction and a definition of the same thing, and, in addition, that the definition neither demonstrates nor proves anything, and that it is not possible to know the what-it-is either by a definition or by a demonstration.

2.8
Reinvestigation of Definition and Demonstration of the What-It-Is

But we must investigate again which of these arguments is correctly stated and which
93a1 not correctly, and what definition is, and whether there can in some way be demonstration and definition of the what-it-is or in no way at all.

Since, as we said,[85] it is the same thing to know what something is and to know the cause of the fact that it is (and the argument for this is that something [A] is the
5 cause, and this cause is the thing [C] itself or something else, and if it is something else, the thing [C] is either demonstrable or indemonstrable, and further, if it is something else and it is possible to demonstrate [C]), it is necessary for the cause to be the middle term [B] and for it [C] to be proved in the first figure; for what is being proved is universal and positive.

One way, then, [of proving the what-it-is] would be that which has just now been
10 reviewed, where the[86] what-it-is is proved through another one. For in the case of the what-it-is, it is necessary for the middle term to be a what-it-is, and in the case of a special affection, for it to be a special affection. So of the essences of the same thing, we will prove the one but not the other. In this way, then, it will not be a demonstra-
15 tion, as was said earlier;[87] instead, it is a logico-linguistic deduction of the what-it-is.

Let us say, then, in what way [a demonstration of the what-it-is] is possible, discussing the issue again from the start. For just as we inquire about the why when we possess the that (although sometimes they also become clear at the same time), but it is not at all possible to know the why before the that, in the same way it is clear that we cannot know the essence of a thing without knowing that the thing is; for
20 it is impossible to know what it is when we are ignorant as to whether it is. As to whether it is, sometimes we possess this coincidentally, and sometimes by possessing something of the thing itself—for example, as regards thunder, that it is a sort of

85. 90a31–34.
86. Reading τὸ.
87. 2.4.

noise in the clouds; as regards an eclipse, that it is a sort of lack of light; as regards a human being, that he is a sort of animal; and as regards soul, that it is something that moves itself.

As regards anything, then, of which we know coincidentally that it is, it is necessary that we possess nothing at all regarding what it is; for we do not even know that it is; and to inquire about what something is without possessing that it is, is to inquire about nothing. But for the things of which we possess something, it is an easier matter. So to the extent that we possess that it is, to that extent we also possess a relation to the what-it-is.

When, then, we possess some grasp of the what-it-is, let the first case be the following. A is eclipse, C is the moon, B is the interposition of the earth. To inquire about whether the moon is eclipsed or not is to inquire about whether B is the case or not. And this is no different from inquiring about whether there is an account of it; and if there is the account, we say that the thing [B] is. (Or, of which of the contradictory pair does the account hold—of its having or not having angles equal to two right angles?)

When we have found out, we know at the same time the that and the why, if we proceed through middle terms.[88] Otherwise, we know the that but not the why. C is the moon, A is eclipse, B is not being able to cast a shadow during a full moon although there is nothing apparent between us and it. Therefore, if B (not being able to cast a shadow during a full moon although there is nothing between us and it) belongs to C, and A (being eclipsed) belongs to B, it is clear that it is eclipsed but why it is eclipsed is not yet clear; and we know that there is an eclipse but we do not know what it is.

When, on the other hand, it is clear that A belongs to C, to inquire about why it belongs is to inquire about what B is—whether interpolation or rotation or extinction of the moon. And this is the account of the other extreme—that is, A in these instances. For an eclipse is the interposition of the earth. What is thunder? Extinction of the fire in the clouds. Why does it thunder? Because fire in the clouds is extinguished. C is clouds, A is thunder, B is extinction of fire. B, then, belongs to C (clouds), for the fire is extinguished in them; and A (the noise) belongs to B; and B is indeed the account of A, the first extreme term. And if there is another middle term for this, it will come from the accounts that have been left aside.

In what way, therefore, the what-it-is is grasped and becomes known has been stated, with the result that no deduction and no demonstration of the what-it-is comes about. However, it is made clear through deduction and through demonstration, with the result that it is neither possible to know the what-it-is without a demonstration, where the cause is something else, nor is there a demonstration of it, as we said in going through the puzzles.[89]

88. Reading διὰ μέσων.
89. 2.2–3.

2.9
Making Clear What Something Is through Demonstration

For some things the cause is something else, of others it is not. So it is clear that in some cases the what-it-is is immediate and a starting-point, and for these one must hypothesize both that they are and what they are, or make this evident in some other way (this is precisely what the arithmetician does; for he hypothesizes both what a unit is and that it is). But for things that have a middle term and for which something else is the cause of their substance, it is possible, as we have said,[90] to make these clear through a demonstration, without demonstrating the what-it-is.

2.10
The Different Sorts of Definition

Since a definition is said to be an account of the what-it-is, it is evident that one sort will be an account of what a name, or some other name-like account, signifies—for example, what "triangle" signifies. When we possess that precisely this thing is, we inquire about why it is. But it is difficult to get hold of things in this way when we do not know that they are. The cause of the difficulty was stated earlier,[91] that we do not even know that they are, except coincidentally. (An account is one in two ways: either by conjunction as the *Iliad* [might be], or by indicating one thing said not coincidentally of one thing.)

One definition, then, of definition is the one just stated, but another is that a definition is an account that makes clear why the thing is. So the former one signifies but **94a1** does not prove, while it is evident that the latter will be like a demonstration of the what-it-is, differing from a demonstration in arrangement. For there is a difference between saying why it thunders and what thunder is. For in the first case one says "because the fire in the clouds is extinguished." But what is thunder? "The noise of fire in the clouds being extinguished." So the same account is said in another way, and in one way it is a continuous demonstration, while in the other way it is a definition.

(The definition of thunder is also "noise in the clouds"; this is the conclusion of the demonstration of its what-it-is.)

The definition of immediate things is the indemonstrable positing of their what-it-is.

Therefore, one sort of definition is an indemonstrable account of the what-it-is; another is a deduction of the what-it-is, differing in inflection from a demonstration; a third is the conclusion of a demonstration of the what-it is.

90. 2.8.
91. 93a24–27.

It is evident, then, from what has been said in what way there is demonstration of the what-it-is and in what way there is not, and of what sorts of things there is one, and of what sorts there is not; and further, in how many ways something is said to be a definition, and in what way it proves the what-it-is and in what way not, and of what sorts of things it does and of what sorts it does not; and further, how it is related to demonstration, and in what way it is possible for there to be demonstration and definition of the same thing and in what way it is not possible.

2.11
The Four Causes as Middle Terms

Since we think we have scientific knowledge of something when we know the cause, and there are four causes (one, the essence; one,[92] what, if certain things hold, it is necessary for it to hold; another, what first produced the movement; the fourth, the for-the-sake-of-which), all of them are proved through the middle term.

For "what, if this thing holds, it is necessary for it to hold" comes about not when one premise is assumed, but when at least two are; and this is so when they have one middle term. So when this one thing is assumed, it is necessary for the conclusion to hold. This is also clear from the following. Why is the angle in a semicircle a right angle? What has to hold for it to be a right angle? Let A be right angle, B half of two right angles, C the angle in the semicircle. Of A (right angle) belonging to C (the angle in the semicircle), then, the cause is B. For B is equal to A and C to B (for it is half of two right angles). If, then, B (which is the half of two right angles) holds, A belongs to C (and this, we said, is for the angle in the semicircle to be a right angle). And this [B] is the same as the essence [of C], in that this is what its account signifies. But then it has also been proved that the middle term is the cause of the[93] essence.

Why did the Persian war with the Athenians come about? What is the cause of the war made against the Athenians? Because they attacked Sardis with the Eretrians; for this first produced the movement. A is war, B is being first to attack, C is the Athenians. B belongs to C (being first to attack belongs to the Athenians), and A belongs to B (for people make war on those who first do them injustice). Therefore, A belongs to B (having war made against them belongs to those who started it in the first place), and this—B—belongs to the Athenians; for they started it first. Therefore, here too the cause—what first produced the movement—is the middle term.

Cases where the for-the-sake-of-which is the cause: For example, why is he taking a walk? In order to be healthy. Why is there a house? In order to preserve the equipment. In the former case for the sake of being healthy, in the latter for the sake of preservation. Why must one take a walk after dinner, and for the sake of what must

92. I.e., the material cause (*Ph.* 195ª15–18, *PA* 677ª18, *Met.* 1013ª5).
93. Reading τοῦ and rejecting <ὄν>.

one do so?—there is no difference. C is taking a walk after dinner, B is food not coming to the surface, A is being healthy. Let it be the case, then, that taking a walk after dinner makes food not come to the surface at the mouth of the stomach, and let this be healthy. For it seems that B (the food's not coming to the surface) belongs to C (taking a walk), and A (being healthy) to B. What, then, is the cause of A—the for-the-sake-of-which—belonging to C? It is B, [the food's] not coming to the surface. And this is, as it were, an account of A; for A will be accounted for in this way. Why does B belong to C? Because being in this state [B] is what being healthy is. (One must exchange the accounts, and in this way each will become more evident.)

Here the events are in the reverse order compared to causes in terms of movement. For there the middle term must come about first, while here C, the extreme, must come about first, although the final thing [to occur] is the for-the-sake-of-which.

But it is possible for the same thing to be both for the sake of something and of necessity—for example, light passing through a lantern. For finer-grained things pass through larger ducts of necessity (if indeed light is produced by passing through) and also for the sake of something (in order that we not stumble about). If it is possible, then, for a thing to be [both for the sake of something and of necessity], is it also possible for a thing to come to be [both for the sake of something and of necessity]? For example, if it thunders both because when fire is extinguished it is necessary for it to sizzle and make a noise, and, as the Pythagoreans say, it is for the sake of threatening the dead in Tartarus in order to make them afraid. There are very many things of this sort, and especially among the things that are composed and produced in accord with nature; for one nature produces them for sake of something, while another does so of necessity. But necessity is twofold; for one is in accord with nature and impulse, while the other is by force or contrary to impulse—as a stone of necessity travels both upward and downward, but not because of the same necessity.

But among the products of thought, some never start up spontaneously—for example, a house or a statue—nor of necessity either, but rather for the sake of something, while others are also due to luck—for example, health and safety. It is most of all among things that admit of being one way or another—when, not due to luck, their coming about is such that the end is good—that they come about for the sake of something, either by nature or by craft. But nothing that is due to luck comes about for the sake of something.

2.12
Causes and Effects

The cause for things that are coming to be, things that have come to be, and things that will be is precisely the same as the one for things that are (for the middle term is the cause)—except that for things that are the case, the cause is [present], for things that have come to be, it has come to be, and for things that will be, it will be. For example,

why has an eclipse come to be? Because the earth has gotten in between. And it is coming to be because the earth is getting in between, and it will be because the earth will be in between, and is doing so because it is there. What is ice? Let it be assumed, then, that it is frozen water. C is water, A is frozen, B (the cause, the middle term) is the complete absence of heat. B, then, belongs to C and A (being frozen) belongs to B. Ice is coming to be when B is coming to be, has come to be when B has come to be, and will be when B will be. Now, what is a cause in this way and what it is the cause of come to be at the same time, whenever they come to be, and when they are, they are at the same time; and the same holds in the case of what has come to be and what will be.

But in the case of things in which [a cause and what it is the cause of] do not come to be at the same time, is it possible, as it seems to us, for one to be the cause of the other in a continuous time? That the cause of this having come to be is that another thing has come to be? That the cause of something's going to be is that something else will be? And of something's coming to be whether something came to be earlier? The deduction, of course, proceeds from what has come to be later (although in these cases too it is things that have [already] come to be that are the starting-point); which is why it is the same way with what is coming to be. It does not proceed from what is earlier—for example, since this has come to be, this came to be later.

And in the case of what will be it is the same way. For in neither an indeterminate nor a determinate time will it be the case that since it is true to say that this has come to be, it is true to say that this later thing has come to be. For in the interval it will be false to say the latter thing, when the former has already come to be. And the same account applies to what will be: since this has come to be, this will be. For the middle term must be of the same descent: for what came to be, it must be something that came to be; for what will be, something that will be; for what is coming to be, something that is coming to be; and for something that is, something that is. But nothing can be of the same descent as both what has come to be and what will be. Further, it is not possible, either, for the intervening time to be neither indeterminate nor determinate; for it will be false to say [that latter thing] in the interval.

But it is necessary to investigate what the connection is that is such that, after the having come to be, the coming to be happens in things. Or is it clear that what is coming to be is not contiguous to what has come to be? For neither is what came to be contiguous to what came to be; for these things are limits and indivisible. Just as, then, points are not contiguous to one another, neither are things that came to be; for both are indivisible. Due to the same thing, then, what is coming to be is not contiguous to what has come to be. For what is coming to be is divisible, while what has come to be is indivisible. Just as, then, a line stands to a point, so what is coming to be stands to what has come to be; for unlimitedly many things that have come to be are present in what is coming to be. (But this must be discussed more clearly in the universal accounts concerning movement.[94])

94. *Ph*. Book 6.

Where things come to be consecutively, then, let this much be assumed about how the middle term is the cause. For here too[95] it is necessary for the middle term and the first term to be immediate. For example, A has come to be since C has come to be (C has come to be later, A earlier; but C is the starting-point because it is nearer to the now, which is the starting-point of time). And C has come to be if D has come to be. If, then, D has come to be, it is necessary for A to have come to be. And C is the cause; for if D has come to be, it is necessary for C to have come to be, and if C has come to be, it is necessary for A to have come to be earlier.

When one takes the middle term in this way, will [the process] come to a stop somewhere at an immediate, or will a middle term always be inserted because of the unlimitedness? For what has come to be is not contiguous to what has come to be, as was said.[96] But it is surely necessary to start, nonetheless, from something that is immediate and first from the present now.

And it is the same in the case of what will be. For if it is true to say that D will be, it is necessary for it to have been earlier true to say that A will be. And the cause of this is C; for if D will be, C will be earlier, and if C will be, A will be earlier. And here too the division will be unlimited in the same way; for things that will be are not contiguous to each other. But here too an immediate starting-point must be assumed.

It is the same way in the case of works [of craft]. If a house has come to be, it is necessary for stones to have been cut and to have been produced. Why? Because the foundation must have come to be if indeed the house has come to be; and if the foundation has come to be, stones must have come to be earlier. Again, if there will be a house, in the same way there will be stones earlier. And it is proved through the middle term in the same way; for there will be a foundation earlier.

But since we see in what comes to be a sort of circular coming to be, it is possible for this to be, if indeed the middle term and the extremes follow each other; for in these cases there is conversion (this was proved in the first accounts[97]), because the
96ᵃ1 conclusions convert; for this is what being circular is. In the case of works [of nature] it appears this way: if the earth has been soaked, it is necessary for vapor to come to be; if vapor came to be, cloud did; if cloud came to be, water did; and if water came to be, it is necessary for the earth to have been soaked; but this was the starting-point, so that it has come around in a circle; for if any one of these holds, another does, and if that one, another, and if that one, the first one.

There are some things that come to be universally (for they either are or come to be in the same way always and in every case), while others do so not always but for the most part—for example, not every male human being gets a beard, but for the most part they do. In such cases, then, it is also necessary for the middle term to hold for the most part. For if A is predicated universally of B and B universally of C, it is also

95. I.e., as in other scientific deductions.
96. 95ᵇ4.
97. 73ᵃ6–20, *APr.* 2.3–5.

necessary for A to be predicated of C always and in every case (for this is what it is to be universal—to hold in every case and always). But it was hypothesized to hold for the most part. Therefore, it is necessary for the middle term, B, also to hold for the most part. Therefore, for things too that hold for the most part there will be immediate starting-points that hold or come to be in the way they do for the most part.

2.13
Division and Definitions

How, then, the what-it-is is given in the terms [of a deduction], and in what way there is and is not a demonstration and a definition of it, has been stated earlier.[98] Let us now say how one must hunt down the things that are predicated in the what-it-is.

Among the things, then, that always belong to each thing, some belong more widely than it, yet do not extend outside the kind. I say that they "belong more widely" if, though they belong to each thing universally, nonetheless they also belong to something else. For example, there are things that belong to every triad but also to non-triads, as being belongs to a triad, but also to what is not a number; but odd too belongs to every triad and belongs more widely (for it also belongs to a pentad), but it does not extend outside the kind; for a pentad is a number, and nothing outside numbers is odd. Things of this sort, then, one must take up to the point where for the first time each one taken belongs more widely, but all of them together do not belong more widely; for it is necessary for this to be the substance of the thing. For example, number belongs to every triad, and so do odd and prime in both ways (both as not being measured by a number and as not being composed of numbers[99]). This, already, is in fact what a triad is: a number that is odd, prime, and prime in this way. For, in the case of each of these, it holds that some also belong to all odd numbers, the last belongs to a dyad too, but all of them together belong to nothing [except a triad].

Since we have made clear above[100] that whatever [affections] are predicated in the what-it-is are necessary[101] (and what is universal is necessary), and in the case of a triad—and of anything else [whose affections] are taken in this way—what is taken is in the what-it-is, these [affections] will of necessity constitute a triad. **96^{b}1**

And that they are its substance is clear from the following. For if this were not the essence of a triad, it would be necessary for it to be, as it were, a sort of kind, either named or nameless. Therefore, it will belong more widely than to the triad. (For let it be hypothesized that a kind is the sort of thing that potentially belongs more widely.) Therefore, if it belongs to nothing other than the indivisible triads, this would be the

98. 2.8–9.
99. One is not a number (*Met.* $1088^{a}6$–8) so if p is prime, there are no numbers n_1 and n_2 such that $p = n_1 + n_2$ or $p = n_1 \times n_2$.
100. $73^{a}34$–37, $^{b}25$–28.
101. Reading ἀναγκαῖα.

being for a triad. (For let it also be hypothesized that the substance of each thing is the last predication of this sort to apply to what is indivisible.) So, in the same way too, for anything else whatsoever, the things proved in this way will be the being for it.

When one is dealing with some whole, one must divide the kind into what is indivisible in form, the primary things—for example, number into triad and dyad. Then one must try to get definitions of these—for example, of straight line, circle, and right angle. And after this, having got what the kind is (for example, qualities or quantities), one must get a theoretical grasp on the special affections through the common primary things. For the coincidents of the things composed of the indivisibles will be clear from the definitions, because the definition and what is simple are the starting-points of all things, and the coincidents belong intrinsically to the simples alone, and they belong to other things in virtue of the simples.

Also, divisions in accord with differences are useful in following this route. In fact, in what way they prove things was stated earlier.[102] But only in the following way will they be useful for deducing the what-it-is.

And yet they might seem, at any rate, to be of no use at all but rather to assume everything from the outset, just as if one had initially assumed things without division. But it makes a difference which of the predicates are predicated first and which later—for example, whether one says "animal tame two-footed" or "two-footed animal tame." For if everything is composed of two things, and if "animal tame" is one thing, and if in turn from this and the difference human being [is composed], or whatever else the one thing turns out to be, it is necessary to postulate having first made the division [correctly].

Further, with a view to omitting nothing in the what-it-is, this is the only possible way to proceed. For when the primary kind has been taken, if one takes one of the lower divisions, not everything will fall under it—for example, not every animal is whole-winged or split-winged, but every winged one is; for it is of this [kind] that this is a difference. And the first difference of animal is that into which every animal falls; and similarly for each of the others, both the kinds outside it and the ones that fall under it—for example, [the first difference of bird is] that into which every bird falls, and of fish that into which every fish does. If one proceeds in this way it is possible to know that nothing has been omitted; otherwise, one will necessarily both omit something and not know it.

But there is no need for the one who is defining and dividing to know everything there is. And yet there are some[103] who say that it is impossible to know what each thing's differences are without knowing that thing, and that without the differences one cannot know each thing; for what it does not differ from it is the same as, and what it does differ from it is distinct from.

102. 2.5, *APr.* 1.31.
103. E.g., Speusippus.

First, then, this is false; for one thing is not distinct from another with respect to every difference; for there are many differences between things in the same form, although not differences with respect to their substance or what they are intrinsically.

Next, when one takes the opposites (that is, the difference) and assumes that everything falls in one or the other, and that what is being inquired about is in one of the two, and one knows this one, it makes no difference whether one knows or does not know the other things of which the differences are predicated. For it is evident that if by proceeding in this way one reaches things that have no further differences, one will have the account of the thing's substance. And that everything falls in the division, if they are opposites that do not have an intermediate, is not a postulate; for it is necessary for everything to be in one of the two, if indeed it is to be[104] a difference of that thing.

To establish a definition through divisions one must aim for three things: one must take the things predicated in the what-it-is, order these as first or second, and ensure that these are all of them.

It is possible to achieve the first of these by being able to establish things through the kind, just as for a coincident by deducing that it belongs.

One will order things as one should if one takes the first term. And one will do this if one takes the term that follows all the others, while not all others follow it; for it is necessary for there to be some such term. Once this is taken, it is the same way now in the case of the lower ones; for the second term will be the first of the others, and the third will be the first of the next ones; for if the highest term is removed, the next will be the first of the others. And similarly in the other cases too.

That these are all the terms is evident from the fact that one takes as the first term in the division that every animal is either this or that, and that this in fact belongs; again one takes the difference of this whole thing; and of the ultimate one there is no further difference—or rather, what is immediately after the ultimate one no longer differs in form from the compound. For it is clear that neither has anything extra been added (for all the terms taken are in the what-it-is), nor has anything been omitted; for it would have to be a kind or a difference. But the kind is the first term, and this was taken together with the differences; and the differences are all grasped; for there is no further later one; for in that case the ultimate one would differ in form, while it was said not to differ.

One must inquire by looking at things that are similar, that is, undifferentiated, and, first, at what they all have that is the same, then one must do this again for the others: those that are the same in kind as the first group and the same in form as each other but distinct in form from the first group. And when, in the case of these, one has got something that is the same in all of them, one must do likewise in the case of the other group, again looking to see in the case of the things taken whether there is something that is the same, until one arrives at a single account; for this will be the

104. Reading ἔσται.

definition of the thing. But if one does not get to one account but to two or more, it is clear that what one is inquiring about is not one thing but several.

I mean, for example, that if we were inquiring about what greatness of soul is, we must look in the case of some great-souled people whom we know to see what one thing they, as such, all have in common. For example, if Alcibiades,[105] Achilles, and Ajax are great-souled, what one thing do they all have in common? They could not endure being treated with wanton aggression; for one made war, one became enraged, and one killed himself. Again, take others—for example, Lysander and[106] Socrates. If in this case it is indifference to good luck or bad luck, taking these two things, I look to see what the same thing is that indifference to luck and not to endure dishonor have in common. And if it is nothing, there will be two forms of greatness of soul.

Every definition is always universal; for the doctor does not say what is healthy for some particular eye, but rather for every eye, or else for some determinate form of eye.

But it is easier to define the particular than the universal, which is why one must proceed from particulars to universals; for in fact homonymies more often escape notice in the case of universals than with undifferentiated things.

And just as in demonstrations something must have been deduced, so too in definitions there must be perspicuousness. And this will be the case if, through the particulars that one has mentioned,[107] one gives a separate definition for each kind—for example, if one defines similarity not for every case but for colors, and for shapes, and sharpness for sound, and in this way proceeds to what is common, being careful not to fall into homonymy.

If one must not argue dialectically by means of metaphors, it is clear too that one must neither define things by means of metaphors nor define what is said by means of metaphors; for then one will necessarily be arguing dialectically by means of metaphors.

2.14
Division and Problems

98ᵃ1 With a view to getting a grasp on problems one must select from the dissections and the divisions,[108] and do the selecting in this way: having posited the kind that is common to all—for example, if animals are what one is getting a theoretical grasp on, one must select whatever belongs to every animal; and once these are taken, one must next select whatever follows every member of the first of the remaining terms—for

105. Reading καὶ.
106. Reading καὶ.
107. Reading εἰρημένων.
108. The reference may be to Aristotle's *Dissections* and *Divisions*, or to some more strictly logical procedures.

example, if this is bird, whatever follows every bird; and in this way one must always select whatever follows the next nearest term; for it is clear that one will now be in a position to say why whatever follows the things falling under the common kind belongs to them—for example, why they belong to a human being or to a horse. Let A be animal, B whatever follows every animal, and C, D, and E animals of certain sorts. It is clear, then, why B belongs to D; for it does so because of A. It is the same way in the case of the others. And the same account always applies to the ones lower down.

At present we are speaking in terms of the common names that have been handed down to us, but we must investigate not only these, but also anything else that may have been seen to belong in common, taking it separately and seeing what it follows and what follows it—for example, both having a third stomach and not having incisor teeth in both jaws follow having horns. Next, see what things having horns follows. For it is clear why what was mentioned will belong to these: for it will belong because they have horns.

Further, another way is to select by analogy. For it is impossible to come up with one identical thing that cuttlefish bone, fish-spine, and animal bone should be called; but there will be things that follow these too, just as if there were some single nature of this sort.

2.15
Problems with the Same Middle Terms

Some problems are the same by having the same middle term—for example, because all are cases of reciprocal replacement. Among these, some are the same in kind, namely, those that have differences in that they belong to different things or in different ways—for example, why does it echo? or why is it seen in a mirror? or why is there a rainbow? For all these are the same problem in kind (for they are all cases of reflection), but they are distinct in form.

Other problems differ in that the middle term of one falls under the middle term of the other—for example, why does the Nile flow more abundantly at the end of the month? Because the end of the month is stormier. And why is the end of the month stormier? Because the moon is waning. These things are related to each other in this way.

2.16
Relations between Causes and Effects

As regards the cause and what it is the cause of, one might be puzzled as to whether when what is caused is present the cause is also present. As, for instance, if a [plant]

sheds leaves or [the moon] is eclipsed, will the cause of its being eclipsed or of its shedding leaves also be present—for example, if the cause is being broad-leaved, or in
98b1 the case of the eclipse, the earth's being in between? For if it is not present, something else will be the cause of these things, and if the cause is present, what it causes is also present at the same time (for example, if the earth is in between, the moon is eclipsed, or if a plant is broad-leaved, it sheds leaves). And if it is this way, they will be present
5 at the same time and will be proved through each other. For let A be sheds leaves, B broad-leaved, and C vine. If, then, A belongs to B (for everything broad-leaved sheds leaves), and B belongs to C (for every vine is broad-leaved), then A belongs to C,
10 that is, every vine sheds leaves. The cause is B, the middle term. But it is also possible to demonstrate that the vine is broad-leaved through its shedding leaves. Let D be broad-leaved, E sheds leaves, and F vine. Then E belongs to F (for every vine sheds
15 leaves) and D to E (for everything that sheds leaves is broad-leaved). Thus, every vine is broad-leaved. And the cause is its shedding leaves.

But if it is not possible for things to be causes of each other—for the cause is prior to what it is the cause of, and the earth's being in between is the cause of the eclipse, but the eclipse is not the cause of the earth's being in between—if, then, the demonstration through the cause is the demonstration of the why, and the
20 one not through the cause is the demonstration of the that, one knows that it is in between but not why it is. But it is evident that the eclipse is not the cause of the earth's being in between, but rather the latter is the cause of the eclipse; for the earth's being in between is present in the account of the eclipse, so that it is clear that it is through the former that the latter is known, and not the former through the latter.

Or is it possible for there to be several causes of one thing? For if in fact it is
25 possible for the same thing to be predicated in the primary way[109] of more than one thing; let A belong to B in the primary way, and also to C, in another primary way, and let these belong to D and E. Therefore, A will belong to D and E, and the cause of its belonging to D will be B, and that of its belonging to E will be C. So, when the cause is present, it is necessary for the thing at issue to be present, but when the thing
30 is present it is not necessary for everything that is a cause to be present—something that is a cause, yes, but nonetheless not everything that is one.

Or if a problem is always universal and the cause is some totality, is what it is a cause of also a universal? For example, shedding leaves is defined for some totality, even one that has forms, and it belongs to these things universally—either to plants or to plants of a certain sort. So, in these cases, both the middle term and what it is
35 the cause of must be equal [in extension] and must convert. For example, why do trees shed leaves? If it is because of the solidification of their liquid, then, if a tree sheds leaves, solidification must be present, and if solidification is present, not in anything whatever but in a tree, shedding leaves is present.

109. 79a38.

2.17
Can One Thing Have Several Causes?

Is it possible that the same thing is not a cause of the same thing in all cases, but **99ª1**
a distinct one, or is that not possible? Surely, if something has been demonstrated intrinsically and not in virtue of a sign or coincidentally, it is not possible; for the middle term is the account of the extreme. But if it has not been demonstrated in this way, it is possible. And it is possible to investigate coincidentally both what it is a cause of and for what (though such things do not seem to be problems). 5

Otherwise, the middle term will have a similar status [to the other terms]: if they are homonymous, the middle term will be homonymous; if they are in the same kind, it will be so too. For example, why do proportionals alternate? For the causes in the case of numbers and in the case of lines are distinct—and also the same: insofar as they are lines, distinct, but insofar as admitting of a certain sort of increase,[110] the same. And it is this way in all cases. But of a color's being similar to a color or a figure 10
to a figure, the causes are distinct in the two cases. For similarity is homonymous in their case; for in the latter case it is presumably having proportional sides and equal angles, but in the case of colors it is that the perception of them is one, or something else of this sort. As for things that are the same by analogy, they will have middle 15
terms that are also the same by analogy.

The cause, what it is the cause of, and for what thing it is a cause are related to each other in the following way. If one takes them individually, what the cause is of extends more widely—for example, having exterior angles equal to four right angles extends more widely than triangle or square, but if one takes them all together, it extends equally (for they are all things that have exterior angles equal to four right 20
angles). And similarly for the middle term. And the middle term is the account of the first extreme, which is why all the sciences come about through definition. For example, shedding leaves both follows vine and has a wider extension, and follows fig and has a wider extension; but it does not have a wider extension than all of them together, but rather an equal one. If indeed one takes the primary middle term, it is an account of shedding leaves. For there will be a primary middle term in both cases 25
(that they are all of this sort); and then a middle term for this (that the sap solidifies, or something else of this sort). What is it then to shed leaves? For the sap to solidify at the junction of the seed.

In schematic terms, one who is inquiring about the relation between the cause and what it is the cause of will give an account this way. Let A belong to every B 30
and B to each of the Ds, but more widely. Then B would belong universally to the Ds (for I call "universal" a term with which they do not convert; and I call "primary universal" a term that taken separately they do not convert with, but that taken all together they convert with and are coextensive with). B, then, is the cause of A for 35

110. I.e., quantitative increase.

the Ds. Therefore, A must extend more widely than B; otherwise, why will B be the cause rather than A?

If, then, A belongs to every E, all of them together will be some one thing distinct from B. For otherwise how will it be possible to say that A belongs to everything that
99b1 E does, but E does not belong to everything that A does? For why will there not be a cause [for A belonging to every E] as there is for A[111] belonging to every D? (But will the Es in fact be one thing? One must investigate this, and let it be C.)

It is possible, then, for there to be several causes of the same thing, but not for
5 things of the same form—for example, the cause of longevity for four-footed animals is their not having bile, while for birds it is their being dry, or some other thing.

2.18
The True Cause Is the Closest One to the Thing

If one does not arrive straightaway at what is indivisible and there is not just one middle term but several, the causes are several too. But which of the middle terms is the cause of the particulars? The one that is primary in the direction of the universal
10 or the one that is so in the direction of the particulars? It is clear indeed that it is the one closest to what it is the cause of. For it is a cause because the primary term falls under the universal—for example, C is the cause for D of B's belonging to it. C, then, is the cause for D of A's belonging to it, but B is the cause for C of A's belonging to it, and for itself of A's belonging to it.

2.19
How We Get a Grasp on Scientific Starting-Points

15 As for deduction and demonstration, what each of them is and how they come about is evident; and at the same time that goes for demonstrative scientific knowledge too, for it is the same thing. But as for the starting-points, how they come to be known and what the state is that knows them will be clear once we have first gone through the puzzles.

We stated earlier[112] that it is not possible to have scientific knowledge through
20 demonstration if one does not know the primary and immediate starting-points. But one might raise some puzzles about knowledge of the immediates, whether it is the same or not the same [as scientific knowledge], and whether there is scientific knowledge of both [non-immediates and immediates] or not,[113] or rather scientific knowledge of one and some other kind of knowledge of the other, and also whether

111. Rejecting the seclusion of A.
112. 72a25–72b4.
113. Reading ἢ οὔ.

the states are not [already] present in us but arise in us, or rather are [already] present in us without our noticing them.

If we possess them, certainly, the situation is absurd; for it follows that we do have bits of knowledge that are more exact than demonstrations without our noticing them. But if we acquire them without possessing them earlier, how can we come to know and to learn them from a not pre-existing knowledge? For this is impossible, as was also said in connection with demonstration.[114] It is evident, therefore, that neither can we possess these states nor can they arise in us when we are ignorant and possess no such state at all.

Therefore, we must possess some sort of capacity, but not one that will be more estimable than these states with respect to exactness. And it is evident that this is indeed the case for all animals. For they have an innate capacity of discernment, which we call "perception." And when a perception is present, in the case of certain animals a persistence of the perceptual affection comes about, while in others it does not. In those animals, then, in which it does not come about, there is no knowledge outside perception, either none at all or none concerning the things about which this persistence does not come about. But in those in which it is present, it is possible, after having perceived, to still possess the perceptual object in their souls. And after many such occurrences, a certain difference then comes about, so that in some animals an account comes about from the persistence of these things, while in others it does not.

From perception, then, comes memory, as we say, and from memory of the same thing when it occurs many times, experience; for memories that are many in number constitute a single experience. And from experience, or from the entire universal having come to rest in the soul, the one beyond the many (this being whatever is present as one and the same in all of them), comes a starting-point of craft knowledge and scientific knowledge—of craft knowledge if it concerns coming to be, of scientific knowledge if it concerns being. These states, then, are neither present in us as determinate ones nor arise in us from other states that are closer to knowledge, but instead come from perception, as in a battle, when a rout occurs, first one man makes a stand, then another does, and then another, until a starting-point[115] has been reached. And, in fact, the soul is the sort of thing that is capable of undergoing this.

But let us say again what was said just now, but not said perspicuously. For when one of the undifferentiated things makes a stand, there is a first universal in the soul (for although one perceives the particular, perception is of the universal—for example, of human being, but not of Callias the human being). Again, on these [universals] a stand is made, until what is without parts and is universal makes a stand—for example, such-and-such sort of animal makes a stand until animal does. And on this a stand is made in the same way. It is clear, then, that it is necessary for

114. 71^a1–11.

115. I.e., when enough men make the stand needed to turn the tide of battle, the rout starts.

us to know the primary things by induction; for in fact this is the way perception produces the universal in us.

But since among the states of thought by which we grasp the truth, some are always true, while others admit of falsehood (for example, belief and rational calculation do, while scientific knowledge and understanding are always true), and no kind [of state of thought] other than understanding is more exact than scientific knowledge, and since the starting-points are better known than demonstrations, and all scientific knowledge involves an account, there will not be scientific knowledge of the starting-points. And since nothing except understanding can be truer than scientific knowledge, understanding will be of the starting-points. This emerges from our investigation of these things and also because demonstration is not a starting-point of demonstration, and so scientific knowledge is not a starting-point of scientific knowledge either. If, then, apart from scientific knowledge we have no true kind [of state of thought] other [than understanding], it will be understanding that is the starting-point of scientific knowledge. And the starting-point will be related to the starting-point[116] as the entire [branch of] scientific knowledge is related to the entire thing [it deals with].[117]

116. I.e., understanding will be related to the starting-point of the scientific knowledge in question.

117. 96ᵃ8–19.

TOPICS*

BOOK 1

1.1
Aim of the Study

The proposed aim of this study is to find a methodical inquiry by which we will be capable of constructing deductions on any problem[1] that is proposed, proceeding from acceptable beliefs, and, when submitting to argument ourselves, of avoiding saying anything contradictory. First, then, we must say what a deduction is, and what its different varieties are, in order to grasp what a dialectical deduction is; for this is what we are inquiring about in the proposed study.

A deduction, then, is an argument in which, certain things being posited, something distinct from the things proposed follows of necessity because of the things proposed. It is a demonstration when the deduction proceeds from things that are true and primary, or are such that our knowledge of them has a starting-point in things that are primary and true, and a deduction is dialectical when it deduces from acceptable beliefs.

The things that are true and primary are those that are persuasive not because of other things but because of themselves (for in the case of scientific starting-points we must not further inquire about why they are so, instead each of the starting-points must be intrinsically persuasive). Acceptable beliefs, by contrast, are things that seem so to everyone, to the majority, or to the wise—either to all of them, or to most, or to the best known and most reputable.

A contentious deduction is one that proceeds from what appear to be, but are not, acceptable beliefs, or an apparent deduction from what are, or what appear to be, acceptable beliefs; for not everything that appears to be an acceptable belief actually is one. For none of the things said to be acceptable beliefs wears this appearance entirely on its face, which is what actually occurs in the case of the starting-points of contentious arguments;[2] for in their case the nature of their falsity is for the most part immediately clear to those capable of seeing even small things. Let us say, then, that

* Translated by C. D. C. Reeve. Text: J. Brunschwig, *Aristote Topiques Livres I–IV, Livres V–VIII* (Paris, 1967, 2007). The title—*Topikôn*—probably derives from the use of places (*topoi*) as mnemonic devices. See 163^{b}22–33.

1. Retaining προβλήματος. See 104^{b}1–17.

2. *SE* 171^{b}29–33.

101ᵃ1 the first sort we mentioned is a contentious deduction and a [genuine] deduction, while the other sort is a contentious deduction, but not a [genuine] deduction, since it appears to deduce, but does not deduce.

Further, beyond all the sorts of deductions just mentioned, there are the fallacies[3] that proceed from things proper to a given science, as happens in the case of geometry and other sciences akin to it. For this mode of argument would seem to be different from the sorts of deductions we mentioned; for someone who draws false diagrams[4] does not deduce from true and primary things, nor from acceptable beliefs either. For they do not fall within the definition; for he does not take [as his starting-points] things that seem so to all, to the majority, or to the wise (whether all of them, or most, or the most reputable); rather, he produces his deduction from premises proper to the science but not true—for example, he produces his fallacy either by defining the semicircles in a way that he should not, or by drawing certain lines in a way in which they should not be drawn.

The foregoing, then, may be taken as an outline of the forms of deductions there are. And as a universal remark both about all the things mentioned and about those we will discuss later, we may say that this will be the extent of our determinations. This is because of our deliberately choosing not to give an exact account of any of these things; rather, our wish is to give an outline of them, since we consider it fully adequate, for the purposes of the proposed methodical inquiry, to be able to know each of them in some way or other.

1.2
Usefulness of the Study

Our next task, after what we have said, is to say how many areas, and also of what sorts, our study is useful in. It is useful, then, in three: in training, in argumentative encounters, and in the philosophical sciences.

That it is useful in training is immediately evident; for if we have a methodical inquiry we will more easily be able to argue dialectically about whatever is proposed. It is useful in argumentative encounters because, once we have cataloged the beliefs of ordinary people, we will engage in conversation with them, not by proceeding from the beliefs of others, but from their own, changing their minds about anything they appear to us to be stating incorrectly. And it is useful in the philosophical sciences because the capacity to go through the puzzles on both sides of a question will make it easier to judge what is true and what is false in each.

Further, dialectic is useful as regards the primary [starting-points] in each science. For it is impossible to say anything about these based on the starting-points proper

3. *SE* 171ᵇ11–22, 171ᵇ34–172ᵃ11.
4. *SE* 171ᵇ12–16.

to the science in question, since these starting-points are prior to everything else; instead, these must be discussed through the acceptable beliefs about each of them. And this is a task that is special to, or, at any rate, characteristic of, dialectic, which, **$101^{b}1$** because of its capacity to stand outside and examine, provides a route toward the starting-points of all methodical inquiries.

1.3
What It Is to Possess the Methodical Inquiry

We will possess the methodical inquiry completely when we possess it as we do in the case of rhetoric, medicine, or other capacities of this sort. For the rhetorically competent person will not try to persuade, nor will the doctor try to cure, on the basis of every mode [of persuasion or of treatment], but if he omits none of the possible ones, we say that he possesses the science adequately.

1.4
What the Methodical Inquiry Is Based On

First, then, we must get a theoretical grasp on the things on which the methodical inquiry is based. If, then, we could grasp how many and what sorts of things arguments are related to, and on what they are based, and how to become well equipped with these, we would have an adequate grasp on what we proposed.[5]

The things arguments are based on are equal in number to, and the same as, the things that the deductions are concerned with. For arguments are from premises, while the things that the deductions are concerned with are problems. And every premise, as well as every problem, indicates either a kind, a special thing, or a coincident; for in fact the difference, since it is of the kind, must actually be classified together with the kind. But since of what is special one part signifies the essence and another part does not signify it, let us divide what is special into both of the parts just stated, and let us call the part that signifies the essence a "definition," while the remaining part, in keeping with the name commonly assigned to them, may be called a "special affection." It is clear, then, from what has been said that, according to the present division, it turns out that there are four in all: special affection, definition, kind, and coincident. But let no one suppose us to be saying that each of these stated by itself is a premise or a problem, but rather it is from these that problems and premises are generated.

A problem is different from a premise in its mode. For said in this way, "Is two-footed terrestrial animal the definition of human?" or "Is animal the kind of human?"

5. $101^{b}5$–6.

it is a premise; but said in this way, "Whether two-footed terrestrial animal is the definition of human or not," it becomes a problem. And similarly in the case of the others. So it makes perfect sense that problems and premises are equal in number; for one makes a problem out of any premise by exchanging its mode.

1.5
What a Definition, a Special Affection, a Kind, and a Coincident Are

We must say, then, what a definition, a special affection, a kind, and a coincident are. A definition is an account that signifies the essence. It is assigned either as an account in place of a name or as an account in place of an account; for it is also possible **102a1** to define some of the things that are [already] signified by an account. Those who merely assign a name, whatever it is, clearly do not assign the definition of the thing, since every definition is an account.

Nonetheless, this sort of thing—for example, that the noble is the appropriate—must also be posited as akin to definition. Similarly, whether perception and scientific knowledge are the same or distinct; for in fact, where definitions are concerned, most of our time is taken up with whether things are the same or distinct. Putting it simply, let us call all things "akin to definitions" that fall to the same methodical inquiry as definitions. And it is immediately clear that all the cases just mentioned are of this sort. For if we are able to argue dialectically that things are the same or that they are distinct, we will also be well equipped to attack definitions in the same way; for by proving that the two things are not the same, we will have done away with the definition. The converse of what we have just said, however, does not hold; for to establish a definition it is not enough to prove that two things are the same, although to disestablish one it is sufficient to prove that they are not the same.

A special affection is one that does not indicate the essence of a thing, belongs to that thing alone, and is counterpredicated of it. Thus it is a special affection of humans to be receptive of grammar; for if someone is human, he is receptive of grammar, and if he is receptive of grammar, he is human. For no one would say that something is a special affection if it admits of belonging to something else—for example, no one would say that sleeping is a special affection of humans, even if at some time it happened to belong only to them. Therefore, if something of this sort were said to be a special affection, it would be said to be such not unconditionally, but rather a special affection at a time, or in relation to something. Being on the right, for example, is said to be a special affection of something at a time, and two-footed is said to be a special affection in relation to something—for example, a special affection of humans in relation to horses or dogs. It is clear that nothing that admits of belonging to something else is counterpredicated of a thing—for example, if something is asleep, it is not necessary for it to be human.

A kind is what is predicated in the what-it-is of many things that differ in form. And let us say that what are predicated in the what-it-is are the sorts of things that it would be fitting to mention if we were asked what the proposed thing is—just as it is fitting in the case of a human, when asked what it is, to say that it is an animal. The problem of whether one thing is in the same kind as another, or in a distinct one, is also akin to the kind; for this sort of problem also falls to the same methodical inquiry as the kind. For if we argue dialectically that animal is the kind of human, and similarly of ox, we will have argued dialectically that they are in the same kind, while if we prove that it is the kind of one and that it is not the kind of the other, we will have argued dialectically that they are not in the same kind.

A coincident is something that is none of these (whether a definition, a special affection, or a kind), yet does belong to the thing. Also, it is what can belong or not belong to one and the same thing—for example, being seated can belong or not belong to the same thing, and so similarly can being pale; for nothing prevents the same thing from being at one time pale, at another time not pale. The second of these two definitions of a coincident is better; for if the first is stated, anyone who is going to comprehend it must already know what a definition, a kind, and a special affection are; while the second definition is complete in itself for knowing what the thing meant is intrinsically.

We may also add to what is coincident the comparisons between one thing and another that are stated in some way that derives from what is coincident—for example, whether the noble or the advantageous is more choiceworthy, or whether the life in accordance with virtue or the life of indulgence is more pleasant, or anything else that might be stated in much the same way as these; for in all such cases, the inquiry arises as to whether the coincident that is predicated belongs to a higher degree to one or to the other.

It is clear from these things that nothing prevents a coincident from becoming a special affection of something at a time or in relation to something—for example, sitting down, which is a coincident, will be a special affection at a time when only one person is sitting down, and when he is not the only one sitting down it will be a special affection of his in relation to those who are not sitting down. So nothing prevents a coincident from becoming a special affection either in relation to something or at a time. Unconditionally, however, it will not be a special affection.

1.6
No Universal Methodical Inquiry

One must not overlook the fact that the things said with regard to a special affection and a kind will all fit a definition too. For when we have proved that what is given

as a definition does not belong solely to what is under definition[6] (as we also do in the case of a special affection), or that it is not the [correct] kind that is assigned in the definition, or that one of the things stated in the account does not belong to the thing (which is just what might also be said in the case of a coincident), then we will have done away with the definition. So, in accord with the account given previously,[7] all the things we have enumerated would be in a way akin to definitions. But one must not, because of this, seek a single universal methodical inquiry applicable to all cases; for this is not an easy thing to find, and if it were found, it would be entirely lacking in perspicuousness and difficult to use for the proposed study. On the other hand, if we were to assign a special methodical inquiry to each of the kinds we have distinguished, on the basis of what is proper to each, a methodical route through the proposed thing could easily be produced. So we must, as was said previously, make an outline division, and as for the rest, we must attach whichever is most proper to each, and call them "akin to definitions," or "akin to kinds." The ones we mentioned[8] have pretty much been assigned to each.

1.7
The Number of Ways in Which Things Are Said to Be the Same

First of all we must determine the number of ways in which things are said to be the same. And sameness, taken in outline, would seem to be divided into three parts. For we usually call things the same in number, in form, or in kind: in number, when the names are several but the thing is one—for example, cape and cloak; in form, when, though the things are several, they are undifferentiated with respect to form—for example, one human and another human, or one horse and another horse (for things of this sort, which fall under the same form, are said to be the same in form); in kind, similarly, those things are the same that fall under the same kind—for example, horse and human.

It might seem that water from the same spring is said to be the same in a way that has some difference from those mentioned. Nonetheless, this too, at any rate, must be placed in the same part as things said to be the same in some way or other with respect to form; for all such things seem to be akin and much the same as each other. For all water is said to be the same in form as all other water because it possesses a certain similarity, and water from the same spring is different in no other way than that the similarity is much more pronounced. That is why we do not separate this

6. Reading τῷ ὑπὸ τὸν ὁρισμόν.

7. 102^a9–10.

8. I.e., the things akin to definition (102^a5–10) that get assigned to the kind *definition*; the things special but not unconditionally so (102^a24–26) that get assigned to the kind *special affection*; and the comparisons that derive from coincidents (102^b14–16) that get assigned to the kind *coincident*.

case from those that are said to be the same in some way or other with respect to a single form.

What is one in number seems to be most of all agreed to be said by everyone to be the same. But even this is usually assigned in several ways. The strictest and primary way is when sameness is assigned by a name or a definition—for example, "cloak" assigned to cape, or "two-footed terrestrial animal" to human. Second, when sameness is assigned by a special affection—for example, "receptive of scientific knowledge" assigned to human, "what by nature spatially moves upward" to fire. Third, when it is assigned from a coincident—for example, "the one seated" or "the musical one" to "Socrates"; for all these mean to signify oneness in number.

That what has just now been said is true may most of all be learned from cases in which we change the ways we call people; for often when we give an order to call someone who is seated, using his name, we change it, when the person to whom we give it happens not to understand us, on the supposition that he will understand us better from a coincident of the person, and so we tell him to call over to us, "the one seated," or "the one talking," clearly taking the same thing to be signified by the name as by the coincident.

1.8
Basis for the Proposed Division of Predicates

Let sameness, then, as was said,[9] be divided into three parts. **103b1**

Of the fact that arguments are based on the things mentioned previously, are through these and for these, one means of persuasion is by induction; for if one were to look at each premise or problem, it would be evident that it has stemmed either from definition, special affection, kind, or coincident.

Another means of persuasion is by deduction. For it is necessary for everything that is predicated of something either to be or not to be counterpredicated of the thing. And if it is counterpredicated, it must be either a definition or a special affection (a definition, if it signifies the essence; a special affection if it does not signify it; for we saw[10] that this is what a special affection is, what is counterpredicated but does not signify the essence). On the other hand, if it is not counterpredicated of the thing, it either is or is not among the things mentioned in the definition of the underlying subject. And if it is among the things mentioned in the definition, it must be either a kind or a difference, since a definition is composed of a kind and differences. But if it is not among the things mentioned in the definition, it is clear that it must be a coincident; for a coincident was said[11] to be what is neither a definition, nor a kind, nor a special affection, but still belongs to the thing at issue.

9. 103a7–8.
10. 102a18–22.
11. 102b4–7.

1.9
The Categories of Predicates

After this, therefore, we must determine the kinds of predication in which the four we mentioned are found. These are ten in number: what-it-is, quantity, quality, relative, where, when, position, having, doing, and being affected. For the coincidents, the kind, the special affections, and the definition will always be in one of these categories; for all premises [produced] through these signify either a what-it-is, a quantity, a quality, or some other category.

It is clear from the nature of the things themselves that what signifies the what-it-is will sometimes signify substance, sometimes quality, and sometimes some other category. For when human is set forth as an example and it says that what is set forth is human or animal, it says what it is and signifies substance. But when white color is set forth and he says that what is set forth is white or color, he says what it is and signifies quality. Similarly, if what is set forth is yard-long length, if he says that what is set forth is yard-long length, he says what it is and signifies quantity. And similarly in the case of the other categories; for each of these sorts of predicate, both when it itself is said of itself and when its kind is said of it, signifies what it is. But when it is said about another thing, it does not signify what it is, but its quantity, quality, or one of the other categories.

So, what arguments are about and based on are these and this many things. How we can get hold of them, and through what means we can be well equipped with them, must be stated next.

1.10
Dialectical Premises

First, therefore, it must be determined what a dialectical premise is and what a dialectical problem is. For not every premise or every problem must be counted as dialectical; for no one with any understanding would propose as a premise what no one believes, or as a problem what is evident to everyone; for the latter involves no puzzle, and the former no one would accept.

A dialectical premise is a making of a question out of what is acceptable, either to everyone, to most people, or to the wise (and, among these, either to all, to most, or to the best known), provided it is not unacceptable; for anyone would accept what seems to be so to the wise, provided it is not contrary to the beliefs of ordinary people. Dialectical premises also include things that are like acceptable beliefs; the contraries of what appear to be acceptable beliefs, when proposed by way of contradiction; and all beliefs that are in accord with the established crafts.

For if it is acceptable that the science of contraries is the same, it would also appear to be acceptable that the perception of contraries is the same. And if it is acceptable

that the craft of grammar is one in number, then the craft of pipe playing is also one in number, while if there are several crafts of grammar, then there are also several of pipe playing; for all these seem to be similar and akin.

Similarly, the contraries of what appear to be acceptable beliefs, when proposed by way of contradiction, will appear to be acceptable beliefs; for if it is acceptable that one must do good to one's friends, it is also acceptable that one must not do them evil. It is contrary that one must do one's friends evil, but by way of contradiction it is that one must not do them evil. Similarly, if one must do good to one's friends, to one's enemies one must not do it. And this is so too by way of contradiction of the contraries; for the contrary is that one must do one's enemies good. It is also the same way in other cases.

And, in juxtaposition, the contrary about the contrary will also appear to be acceptable. For example, if one must do good to one's friends, one must do evil to one's enemies. (To do good to one's friends might also appear to be contrary to doing evil to one's enemies, but whether this is truly so or not will be stated in our discussion of contraries.[12])

It is also clear that whatever beliefs are in accord with crafts are dialectical premises; for anyone would accept the things believed by those who have investigated these crafts—for example, a doctor about issues in medicine, or a geometer about those in geometry, and similarly in other cases.

1.11
Dialectical Problems

A dialectical problem is a speculation, directed either to choice and avoidance or to truth and knowledge (either by itself or when working together with something else of this sort), about which people believe nothing either way, or ordinary people believe in a contrary way to the wise, or the wise to ordinary people, or each of them to themselves. For it is useful to know some problems only in relation to choice and avoidance (for example, whether pleasure is choiceworthy or not), while it is useful to know others only in relation to knowledge (for example, whether the cosmos is eternal or not). But others are intrinsically of no use in relation to either of these but work together with some things of this sort; for there are many things that we do not wish to know intrinsically, but rather for the sake of other things, in order that, through them, we come to know something else. **$104^{b}1$**

Problems also exist where there are contrary deductions (for there is a puzzle as to whether it is so or not so, because there are persuasive arguments on both sides), as well as those we have no arguments about, because they are so large, thinking that it is difficult to give the why—for example, whether the cosmos is eternal or not; for one could also inquire about things of that sort.

12. $112^{b}27$–$113^{a}19$.

Let problems and premises, then, be determined as has been stated.

A thesis is an unacceptable supposition of someone well-known for philosophy—
20 for example, that contradiction is impossible (as Antisthenes used to say), or that everything moves (according to Heraclitus), or that what is is one (as Melissus says); for to give thought to it when some random person declares things contrary to our beliefs is simpleminded. Or: something contrary to our beliefs for which we have an argument—for example, that not everything that is either has come to be or is
25 eternally, as the sophists say;[13] for a musician who is grammatical is so without having become so or being so eternally; for even if someone does not believe this, he might believe it because of having an argument.

A thesis, then, is also a problem, but not every problem is a thesis, since some
30 problems are such that we have no belief about them either way. That a thesis is also a problem is clear; for it is necessary from what has been said either that ordinary people disagree with the wise about a thesis, or that one or the other lot disagrees among themselves, since a thesis is a certain unacceptable supposition. As things
35 stand, pretty much all dialectical problems are called "theses." But let it make no difference whatever they are called; for it is not because we wish to make up names that we have distinguished them in this way, but in order that we not fail to consider
105ᵃ1 whatever differences there actually are of them.

We must not, however, look at every problem or every thesis, but rather those that someone might puzzle over who is in need of arguments, not punishment or perception;[14] for those who puzzle over "whether one must honor the gods and love one's parents or not" need punishment, while those who puzzle over "whether snow is white or not" need perception. Nor, indeed, must one look at those whose demonstration is near at hand, or those whose demonstration is too remote; for the former involve no puzzle, while the latter involve more of one than is in accord with [dialectical] training.

1.12
Deduction and Induction

10 Having determined these things, then, we must distinguish how many forms of dialectical argument there are. One is induction, another deduction. And what deduction

13. The argument referred to is apparently this: (1) Socrates was musical and became grammatical. (2) Therefore, Socrates, being musical, is grammatical. (3) Therefore, Socrates, being grammatical, is musical. (4) Socrates has not always, being grammatical, been musical. (5) Therefore, it must be that Socrates, being grammatical, has become musical. (6) Therefore, being musical, Socrates became musical and, being grammatical, he became grammatical. (7) Therefore, Socrates was musical before he became musical and grammatical before he became grammatical. (8) But Socrates was not always or eternally either musical or grammatical.
14. *NE* 1179ᵇ23–1180ᵃ5, *Ph.* 254ᵃ24–33.

is was stated previously.[15] Induction is the route from particulars to the universal—for example, if a ship's captain with scientific knowledge is the most excellent one, and so with a charioteer, then, in general, the person who has scientific knowledge about anything is best. Induction is more persuasive, more perspicuous, better known by perception, and common to ordinary people, but deduction has greater force and is more effective against those skilled in logico-linguistic disputation.

1.13
The Four Instruments

Let the kinds, then, of the things arguments are about and on which they are based be determined as was stated previously.[16] The instruments through which we will become well equipped with deductions are four: one is getting hold of premises; the second is being able to distinguish in how many ways something is said of things; the third is finding the differences; and the fourth is the investigation of likeness. There is a way in which the last three of these are also premises, since it is possible to make a premise of each of them—for example, that either the noble, the pleasant, or the advantageous is choiceworthy; or that perception differs from scientific knowledge in that it is possible to get the latter back again after losing it but not the former; or what conduces to health is related to health as what conduces to the good state is to the good state. The first is a premise from what is said to be something in many ways; the second is one from differences; the third is one from like things.

1.14
(1) Getting Hold of Premises

Premises must be selected in as many ways as were determined in connection with premises, by having ready to hand the beliefs either of everyone, of most, or of the wise (and of these, the beliefs of all, most, or the best known), provided they are not contrary to the apparent ones, and whatever beliefs are in accord with the crafts (but one must propose even the contraries of apparently acceptable premises by way of contradiction, as was stated previously[17]). **105b1**

It is also useful in selecting these to produce not only the ones that are acceptable but the ones that are like them—for example, that the perception of contraries is the same (for the science of them is too), or that we see by taking something in, not sending something out (for it is this way too in the case of the other perceptual modalities, since we hear by taking something in, not sending something out, taste in

15. 100a25–27.
16. 1.4–12.
17. 104a8–15.

the same way, and it is the same way too in the case of the others). Further, whatever appears to be so in all or in most cases must be taken as a starting-point and seeming posit (for those who have not seen in which case it is not so accept it).

One must also select premises from written accounts and produce catalogs of them concerning each kind of subject, putting them under separate headings—for example, concerned with goodness, concerned with life, and concerned with every sort of goodness—starting with the what-it-is. And one must also take note of the beliefs of particular people—for example, that it was Empedocles who said that there are four elements of bodies (for anyone might accept what was said by a reputable person).

In outline, there is a three-part division of premises and problems; for some premises are ethical, some are natural scientific, and some are logico-linguistic. Premises such as the following are ethical—for example, whether one must obey one's parents rather than the laws, if they disagree; logico-linguistic—for example, whether the science of contraries is the same or not; natural scientific—for example, whether the cosmos is eternal or not. And similarly for the problems. What each of the ones mentioned is like, though, is not easily given in definitions concerning them, and one must try to come to know each of them by the intimacy that comes through induction, examining them by reference to the paradigms that were mentioned.

In relation to philosophy, premises and problems must be treated in accord with truth, but dialectically, in relation to belief.

All premises must be selected in the most universal version possible, and one premise made into many—for example, "the science of opposites is the same" must be made into "the science of contraries is the same, and the science of relatives is." Then these premises must in turn be divided up in the same way, as far as is possible to divide them up—for example, "the science of good and bad is the same, and that of white and black, and that of cold and hot." And similarly in the case of the others.

1.15
(2) Distinguishing in How Many Ways Something Is Said of Things

106a1 About premises, then, the foregoing remarks are sufficient. As regards the number of ways [something is said to be something], we must not only treat those that are said to be something in distinct ways but also try to give accounts of them—for example, not only that justice and courage are said to be good in one way, while what conduces to a good state and what conduces to health are said to be so in a distinct one, but also that the former are said to be such by being themselves of a certain sort, while the latter are said to be such by being productive of something, and not by being themselves of a certain sort. And in like manner in the other cases.

Whether the ways in which something is said to be something are many or one in form is something one must get a theoretical grasp on by means of the following:

First, look at the contrary to see whether it is said of things in many ways and if they disagree either in form or in name. For sometimes their distinctness is immediately visible in their very names—for example, to sharp in sound dull is contrary, while in a body blunt is. It is clear, then, that what is contrary to sharp is said of things in many ways. But if that is so, sharp is too; for in each of these cases a distinct thing will be what is contrary. For the same sharp will not be contrary to blunt and dull; yet sharp is contrary to each. Again, to dull in sound sharp is contrary, but in a body round is, so that dull is said of things in many ways, since its contrary is too. And similarly to noble in the case of an animal ugly is the contrary, while in the case of a house ramshackle is, so that noble is homonymous.

In some cases there is no disagreement whatever in the names, but in the form, the difference in them is immediately clear—for example, in the case of bright and dark. For a voiced sound is said to be bright or dark, and similarly a color. In names, these do not disagree at all, but in the form the difference in them is immediately clear; for a color and a voiced sound are not said to be bright in the same way. This is also clear through perception; for the same perceptual modality perceives things that are the same in form, but we do not discern bright in the case of a voiced sound and of a color by the same perceptual modality; rather, we perceive the latter by sight and the former by hearing. It is the same way with sharp and dull in tastes and in bodies: we discern the latter by touch, the former by taste. For these too do not disagree in name, neither in the case of themselves nor in the case of their contraries; for in fact dull is what is contrary to each.

Further, see whether there is something that is contrary to one, while to the other there is simply nothing—for example, to the pleasure that derives from drinking the pain that derives from being thirsty is contrary, while to the pleasure that derives from getting a theoretical grasp on the fact that the diagonal is incommensurable with the side nothing is contrary. So things are said to be a pleasure in many ways. And hating **106b1** is contrary to loving in thought, while to loving as bodily activity nothing is.[18] It is clear, then, that loving is homonymous.

Further, in the case of intermediates, see whether there is something intermediate to one [pair of contraries] but nothing to the other, or if there is something in both cases, but not the same thing—for example, between bright and dark in color, there is gray, but in sound there is none, unless it is husky, as some people say that the husky voice is intermediate. So bright is homonymous, and similarly dark.

Further, see whether there are several intermediates for one pair but one for the other, as in the case of bright and dark; for in the case of colors the intermediates are many, while in the case of voiced sounds there is one, husky.

Further, look at the contradictory opposite to see whether it is said of things in many ways; for if it is said of things in many ways, what is opposite to it will also be said of things in many ways. For example, not seeing is said of things in many ways,

18. The contrast is like that between our love as a feeling or emotion and making love.

one of which is not having sight and the other not activating sight. But if not seeing is said of things in many ways, then seeing must be too; for to each not seeing something is opposed: having sight to not having it, and activating sight to not activating it.

Further, look at things said by way of privation and having; for if one of these is said of things in many ways, the remaining one is too. For example, if having perception is said of things in many ways, as soul and also as body, lacking perception will also be said in many ways, as soul and also as body. And that it is by way of privation and having that the things just mentioned are opposed is clear, since it is natural for animals to have each of the two sorts of perception both as soul and as body.

Further, one must look at the inflections. For if justly is said of things in many ways, just will be said of things in many ways too; for there is a just corresponding to each justly. For example, if justly is said of both judging in accord with one's own consideration and judging as one should, it is similar too with just. In like manner, if conduces to health is said of things in many ways, then conducively to health will be said in many ways too. For example, if what conduces to health is productive of, protects, or is a sign of health, then conducively to health will be productively, protectively, or by way of being a sign of it. And similarly in other cases, when something is itself said of things in many ways, an inflection derived from it will also be said of things in many ways, and if the inflection is, so is it itself.

Look too at the kinds of predication of the name to see whether these are the same in all cases; for if they are not the same, it is clear that the name mentioned is homonymous. For example, the good in foods is what is productive of pleasure, in medicine, what is productive of health, while in the case of the soul, it is being of a certain sort (for example, temperate, courageous, or just), and similarly in the case of a human being. Sometimes it is a time—for example, what is opportune (for what is opportune is said to be good). Often, it is a quantity—for example, in the case of the moderate amount (for the moderate amount is also said to be good), so that good is homonymous.

In like manner, bright is a color in the case of a body, but in the case of a voiced sound it is what is easy to hear. Sharp is much the same way; for in like manner, it is not said in the same way of things in all cases; for it is the rapid sound that is sharp (as those who do arithmetical harmonics say[19]), but it is the angle less than a right one that is sharp [acute], or a knife with a sharp-angled edge.

Look too at the kinds of things that fall under the same name to see whether they are distinct and not one subordinate to another. For example, donkey: both the animal and the implement;[20] for the account that corresponds to the name is distinct for these; for the one will be said of things as animal of a certain sort, the other as implement of a certain sort. But if the kinds are one subordinate to another, it is not necessary for the accounts to be distinct. For example, of raven both animal and bird are kinds. When we say that a raven is a bird, then, we also say that it is a certain sort

19. I.e., the Pythagoreans.

20. I.e., a sort of steam engine.

of animal, so that both kinds are predicated of it. Similarly, when we say that a raven is a flying two-footed animal, we say that it is a bird. In this way too, then, both kinds are predicated of the raven. But in the case of kinds not subordinate one to another, this does not happen; for when we say that something is an implement, we do not say that it is an animal; nor, when we say that it is an animal, do we say that it is an implement.

Look not only at the proposed thing to see whether the kinds are distinct and not one subordinate to another, but also its contrary; for if its contrary is said of things in many ways, it is clear that the proposed thing is too.

It is also useful in the case of a definition to look to see what comes about when it is of a composite—for example, of bright body or bright sound; for if what is special is subtracted, the same account must remain. But this does not happen in the case of homonyms—for example, in the case of the ones just mentioned; for the one is body having such-and-such color, and the other is sound that is easy to hear. When we subtract body and sound, then, what remains in each is not the same. But it certainly should have been, if indeed the white said in each case was synonymous.

But often something homonymous follows along unnoticed in the accounts themselves. That is why one must in fact look at the accounts too. For example, if someone says that what is a sign of and productive of health is what is in moderation, one must not give up but rather must look to see what in each case he has meant by "what is in moderation"—for example, if the one is of such a quantity as to produce health and the other is such as to signify of what sort the state is.

Further, one must look to see whether they are not comparable with respect to more or equally—for example, a bright sound and a bright cloak, or a sharp taste and a sharp sound; for these are not said to be equally bright or equally sharp, nor is one said to be more so than the other, so that bright and sharp are homonymous. For all synonymous things are comparable; for either they will be said to be equally such, or one more so than the other.

Since the differences of kinds that are distinct and not one subordinate to another are also distinct in form, for example, of animal and of scientific knowledge (for the differences of these are distinct), look to see whether the things falling under the same name are differences of kinds that are distinct and not one subordinate to another—for example, sharp [said] of a voiced sound and of a body; for one voiced sound is differentiated from another by sharpness, and similarly one body from another. So sharp is homonymous; for these sharpnesses are differences of kinds that are distinct and not one subordinate to another.

Again, see whether the things falling under the same name have themselves distinct differences—for example, those of color in the case of bodies and in pieces of music; for the differences of color in the case of bodies are dilating and contracting of sight,[21] while in the case of pieces of music, the differences are not the same. So color is homonymous; for the same things have the same differences.

21. Plato, *Timaeus* 67d–e.

Further, since the form is not a difference of anything, look at the things falling under the same name to see whether one is a form and the other a difference—for example, bright in the case of bodies is a form of color, while in the case of sounds it is a difference; for one sound is differentiated from another by being bright.

1.16
(3) Finding Differences

One must investigate the many ways [in which one thing may be said of another], then, by means of these and the like [procedures].

As for differences, one must look at those within the same kinds in relation to each other, for example, in what respect justice differs from courage, or practical wisdom from temperance (for all these are in the same kind), and in those from one kind in relation to another, if they are not too very far apart (for example, in what respect perception differs from scientific knowledge); for in the case of things that are very far apart, the differences are immediately clear.

1.17
(4) Seeing Similarities

As for similarity, one must first look at it in the case of things in distinct kinds, on the supposition that as one is to one, so the other is to the other (for example, as scientific knowledge is to the scientifically knowable, so perception is to the perceptible), and that as one thing is in one, so another is in another (for example, as sight is in the eye, so understanding is in the soul, or as calm is in the sea, so stillness is in the air). We must train ourselves above all on things that are very far apart; for in the case of the rest, we will more easily be able to see the points of similarity. And one must also look at things in the same kind to judge whether anything that is the same belongs to all of them—for example, to human, horse, and dog; for to the extent that the same something belongs to all of them, to that extent they are alike.

1.18
Usefulness of the Last Three Instruments

It is useful, on the one hand, to have looked at how many ways something is said of things with an eye to perspicuousness (for someone would better know what he is positing, if it had been made evident in how many ways it is said of things) and to making deductions that are related to the thing at issue itself and not to a name; for when it is unclear in how many ways something is said of things, it is possible that the

answerer and the questioner are not directing their thought to the same thing. But when it has been made evident in how many ways it is said of things, and to which of them the answerer is directing his thought in positing it, the questioner would appear ridiculous, if he did not make his argument about this. It is also useful with an eye to not getting trapped by a fallacy and to trapping others by a fallacy. For if we know in how many ways something is said of things, we will not be trapped by a fallacy ourselves, but rather will know if the questioner did not produce his argument in relation to the same thing [as we answered about]. And when we ourselves are questioning, we will be able to trap others by a fallacy, if the answerer should happen not to know in how many ways something is said of things. This is not possible in every case, but only when some of the things said in many ways are true and others false. This mode [of argument], however, is not proper to dialectic, which is why dialecticians must altogether avoid this sort of thing, arguing dialectically regarding a name, unless one is otherwise wholly unable to argue dialectically about the proposed thing.

Finding differences, on the other hand, is useful both with an eye to deductions about same and distinct and to knowing what each given thing is. That it is useful with an eye to deductions about same and distinct is clear (for when we have found any difference whatever between the things proposed, we will already have proved that they are not the same); and it is useful in relation to knowing what something is, because we usually separate the special account of the substance of each thing by the differences that are proper to it.

Getting a theoretical grasp on similarity is useful in relation to inductive arguments, deductions from a hypothesis, and to giving definitions:

It is useful in relation to inductive arguments, because it is by induction from particulars, in the case of their similarity, that we claim we have a right to bring in the universal; for it is not easy to do an induction if we do not know the points of similarity.

It is useful in relation to deductions from a hypothesis, because it is an acceptable belief that as it is in the case of one of a number of like things, so it is in the case of the rest. So, whichever of these we may be well equipped to argue dialectically about, we will obtain an agreement beforehand that however things stand in their case, so they also stand with the proposed thing. And when we have proved the former, we will also have proved what was proposed on the basis of a hypothesis; for it was by hypothesizing that however things stand in the case of these, so they also stand with the proposed thing, that we produced our demonstration.

It is useful in relation to giving definitions, because if we can see what is the same in each case, we will not be puzzled as to what kind the proposed thing falls into when we are defining it; for of what is common, what is predicated in the what-it-is would most likely be the kind.[22] In the same way, getting a theoretical grasp on the

22. Since the difference—the other thing predicated in the what-it-is—is more likely to distinguish than to be something common.

similarity in things that are very far apart is also useful in relation to definitions—for example, that a calm in the sea and a stillness in the air are the same (for each is a quietness), or a point in a line and a unit in a number (for each is a starting-point). So, if we assign what is common to all of them as the kind, we will not seem to be defining in an irrelevant way. And, in fact, those who define things[23] are pretty much accustomed to giving definitions in this way; for they say that the unit is the starting-point of number and that the point is the starting-point of line. It is clear, then, that they place them in the kind that is common to both.

These, then, are the instruments through which deductions are made. The topics in relation to which the ones mentioned are useful are as follows.

BOOK 2

2.1
Issues Concerning Problems

Among problems, some are universal, others particular. Examples of universal ones: every pleasure is good, no pleasure is good. Examples of particular ones: some pleasure is good, some pleasure is not good. And the procedures for universally establishing and disestablishing are common to both kinds of problems; for when we have proved that F[24] belongs to all, we will also have proved that it belongs to a particular one; and similarly, if we prove that F does not belong to any, we will also have proved that it does not belong to all. First, then, we must speak about the procedures for universally disestablishing,[25] because such procedures are common both to universal and to particular problems, and because people more often introduce theses consisting in F belonging than in F not belonging, while those who are arguing dialectically with them seek to disestablish this.

It is very difficult, however, to convert a name deriving from a coincident that is proper to something; for belonging in some way but not universally is possible only in the case of coincidents. For when it derives from a definition, a special affection, or a kind, it is necessarily convertible. For example, if it belongs to something to be a two-footed terrestrial animal, it will be true by conversion to say that it is a two-footed terrestrial animal. Similarly, if the name derives from a kind; for if being animal belongs to something, then it is an animal. And the same things are so in the case of a special affection; for if being receptive of grammar belongs to something, it will be receptive of grammar. For none of these admits of partly belonging or not

23. Probably Platonists. See *Met.* 987b1–9, 987b29–33, 1039a24–26.

24. F is a supplied variable whose particular instances are the things said to belong.

25. These (embodied in topics), with some identified as also useful for establishing, seem to remain in focus until 3.6, where the application to particulars is discussed.

belonging, but must unconditionally belong or not belong. In the case of coincidents, however, there is nothing to prevent one—for example, whiteness or justice—from partly belonging, and so it is not enough to prove that whiteness or justice belongs to someone in order to prove that he is white or just; for it is open to dispute whether he is [only] partly white or partly just. So in the case of coincidents, conversion is not necessarily valid.

We must also determine the errors that occur in problems, because these are twofold, caused either by false statement or by violation of the established style of speech; for those who make false statements, and say that F belongs to something it does not belong to, commit error; while those who call things by the names of other things—for example, calling a plane-tree "human"—violate the established use of names.[26]

2.2
Various Topics

One topic[27] is looking to see whether one's opponent has assigned as a coincident something that belongs in some other way. This error is most often committed in regard to kinds—for example, if someone were to say that to be a color is a coincident of white; for being a color is not a coincident of white, but rather the kind of it is color. It is possible, of course, for an opponent in fact to determine his use of the name in what he posits—for example, saying that being a virtue is a coincident of justice. But often, and without such a determination, it is immediately clear that **$109^{b}1$** he has assigned the kind as a coincident—for example, if someone were to say that whiteness is colored or that walking is in movement. For a predicate of the kind is never said paronymously of the form, but always the kinds are predicated synonymously of the forms; for the forms take on both the name and the account of their kinds. A person, then, who says that white is colored has not assigned colored as its kind, since he has spoken paronymously, nor as a special affection, nor as a definition; for the definition and special affection of a thing belong to nothing else, while many other things are also colored—for example, a piece of wood, a human, a horse. It is clear, then, that he assigns colored as a coincident.

Another topic is to examine cases where F has been said to belong to all or to none. Look at them form by form and not in their unlimited number; for then the inquiry will proceed in a more methodical way and in fewer steps. And one must look at, and start with, the primary ones,[28] and then proceed step by step toward the indivisible ones. For example, if a person has said that of opposites the science is the same, one must look to see whether of relatives, of contraries, of privation and having, and of things said by way of contradiction the science is the same. And if the

26. $140^{a}3$–17, $148^{b}16$–22.
27. Reading τόπος.
28. I.e., the ones that are the most universal. See $105^{b}31$–37.

situation is not yet evident at this level, one must again divide these until one comes to the indivisible ones, and see, for example, whether it be so of just and unjust things, the double and the half, blindness and sight, or being and not being. For if in any case it is proved that the science is not the same, we will have done away with the problem. One proceeds in the same way if a predicate belongs in no case. This topic is convertible for purposes of establishing and disestablishing. For if, when we have introduced a division, F appears to belong in all or in many cases, one must demand that the opponent posit the universal, or else bring an objection and show in what case it is not so; for if he does neither of these, not positing it will make him appear absurd.

Another topic is to produce accounts both of a coincident and what it is a coincident of, either of both, each taken singly, or else of one of them, and then look to see whether anything untrue in these accounts has been assumed as true. For example, if the problem is whether it is possible to do injustice to a god, ask: "What is doing injustice?" For if it is to harm voluntarily, it is clear that it is not possible for a god to suffer injustice; for it is not possible for a god to be harmed. And if it is whether the excellent person is envious, ask: "What is the envious person and what is envy?" And if envy is pain at the apparent doing well of some decent person, it is clear that the excellent person is not envious; for then he would be base. And if it is whether the indignant person is envious, ask: "What is each of them?" For thus it will be immediately evident whether what was stated is true or false. For example, if the envious person is the one who is pained at good people's doing well, and the indignant person is the one who is pained at bad people's doing well, it is clear that the indignant person would not be envious. One must also replace the names in the accounts with their accounts, and not stop until one comes to one that is known; for often, though the whole account has been assigned, what is being inquired about is not yet clear, while if an account is stated of one of the names in the account, it becomes clear immediately.

Further, one must make the problem into a premise for oneself and then bring an objection; for an objection will serve as an attack against the thesis. This topic is pretty much the same as the topic that one must look into cases where F is said to belong in all or in none of something, but it differs in its mode.

Further, one must determine what sorts of things must be called what ordinary people call them and what sorts must not; for this is useful both for establishing and for disestablishing something. For example, one must say that the things at issue must be named using the names as ordinary people do, but that when we ask which of the things at issue are of such-and-such a sort or not of such-and-such a sort, one must no longer turn one's attention to ordinary people. For example, one must say that to conduce to health is to be productive of health, as ordinary people do, but when it comes to whether the proposed thing is productive of health or not, one must no longer name it as ordinary people do, but as the doctor does.

2.3
Topics Relating to Things Said in Many Ways

Further, if F is said of things in many ways, and it has been proposed that it belongs or that it does not belong to something, one must prove it to do so or not to do so in one of the ways, if one cannot prove it in both.[29] This [topic] must be used in cases that escape notice; for if it does not escape notice that F is said of things in many ways, the opponent will object that the very one he raised a puzzle about has not been dialectically argued against but rather the other one. This topic is convertible both for purposes of establishing and for purposes of disestablishing. For if we wish to establish, we will prove that in one way F belongs, if we cannot prove it belongs in both; while if we are disestablishing, we will prove that in one way F does not belong, if we cannot prove it does not belong in both.

Except, in disestablishing there is no need to argue dialectically from something that is agreed to, either when F is said to belong to all or to none; for if we prove that F does not belong to something (whatever it is), we will have done away with its belonging to all. Similarly, if we prove that F belongs to one thing, we will do away with its belonging to none. If, however, we are establishing, we must obtain an agreement beforehand that if F belongs to some thing (whatever it is), it belongs to every one, provided this claim is a persuasive one. For it is not enough for purposes of proving that it belongs to all to argue dialectically that it belongs to one—for example, if the human soul is immortal, all soul is immortal. So an agreement must be obtained beforehand that if some soul (whatever it is) is immortal, all soul is immortal. This is not to be done in every case, but only when we are not well equipped to state a single argument that applies to all cases in common, as the geometer can that the triangle has its angles equal to two right angles.

But were it not to escape notice that F is said of things in many ways, distinguish in how many ways it is said, both when disestablishing and when establishing. For example, if what must be done is what is advantageous or what is noble, one must try to establish or to disestablish both concerning the proposed thing—for example, proving that it is both noble and advantageous, or that it is neither noble nor advantageous. But if it is not possible to prove both, one must prove one, and add a sign that while in one way it is so, in the other it is not so. The same argument also applies when the number of ways distinguished is more than two.

Again, there are those Fs that are said of things in many ways, not homonymously, but in some other way. For example, the science of many things is one, in the way one thing is the end, another what furthers the end—for example, medicine is the science both of producing health and of dieting; or in the way that both are ends, as the science of contraries is said to be the same (for one is no more an end than the other); or intrinsically and coincidentally—for example, the triangle has its angles equal to

29. For simplicity, Aristotle is supposing that the many ways are actually just two.

two right angles intrinsically, but the equilateral has them so coincidentally: for it is coincidental to the equilateral to be a triangle,[30] and it is by this that we know that it has angles equal to two right angles. If, then, it is not possible in any of these ways for the science of many things to be the same, it is clear that this is wholly impossible; or, if it is possible in some way, it is clear that it is possible. One must distinguish as many ways as are useful. For example, if we wish to establish something, we must put forward the sorts in which it is possible, and distinguish only those that are useful for establishing something. But if we wish to disestablish it, we must do so with those in which it is impossible, and leave the rest aside. One must also do this when the number of ways in which F is said of things escapes notice.

Also, that this is, or is not, of [or for] that must be established on the basis of the same topics—for example, that this science is of that, either as an end or as what furthers the end, as what is coincidental, or, again, as what is not of something in any of these ways. And the same argument also applies concerning appetites and whatever else is said to be of [or for] several things; for an appetite that is for a certain thing may be for it as an end (for example, for health), or as what furthers the end (for example, for taking medicine), or as what is coincidental, as in the case of wine, the lover of sweet things has an appetite for it not because it is wine but because it is sweet. For he has an appetite intrinsically for the sweet, but coincidentally for the wine; for if it is dry, he no longer has an appetite for it. Hence his appetite for it is coincidental.

This topic is useful in the case of relatives; for cases of this sort are pretty much cases of relatives.

2.4
Additional Topics

Further, there is substituting for a name one that is better known—for example, substituting "perspicuous" in a supposition for "exact," and "meddlesome person" for "busybody"; for the thesis becomes easier to attack when what is stated is better known. This topic is also common both to establishing and to disestablishing.

In order to prove that contraries belong to the same thing, look at its kind. For example, if one wishes to prove that there is correctness and error with regard to perception, and to perceive is to discern, and discerning can be done correctly or incorrectly, then there would be correctness and error with regard to perception too. In the present instance, the demonstration proceeds from the kind and is with regard to the form; for discerning is the kind of perceiving; for the one who perceives discerns in a way. But it may proceed in the contrary direction, from form to kind; for

30. The essence of the equilateral involves having three equal sides, but makes no reference to angles. Thus it is an intrinsic coincident of it (something demonstrable from its essence but not part of it) that it is a triangle.

whatever belongs to the form belongs also to the kind—for example, if there is a base and an excellent scientific knowledge, there is also a base and an excellent disposition; for disposition is the kind of scientific knowledge.

The first topic is false for purposes of establishing something, but the second is true. For it is not necessary for whatever belongs to the kind to belong also to the form; for animal is winged and two-footed, but human is not. But whatever belongs to the form does necessarily belong also to the kind; for if human is excellent, animal is excellent too. On the other hand, for purposes of disestablishing something, the first topic is true, but the second is false; for all that do not belong to the kind do not belong to the form either, but those that do not belong to the form do not necessarily not belong to the kind.

It is necessary for those things of which the kind is predicated to have one of its forms predicated of them too, and those things that are possessed of the kind or are paronymously said to be what they are from the kind must also be possessed of one of its forms or be paronymously said to be what they are from one of its forms (for example, if scientific knowledge is predicated of something, then grammatical or musical knowledge, or knowledge of one of the other sciences, will also be predicated of it; and if anyone possesses scientific knowledge or is paronymously said to be what he is from scientific knowledge, he will also possess grammatical or musical knowledge or knowledge of one of the other sciences, or will be paronymously said to be what he is from one of them—for example, a grammarian or a musician. And since that is so, if a thesis is stated that derives something in any way from a kind (for example, that soul is moved), look to see whether it is possible for soul to be moved with any of the forms of movement—for example, whether it can grow, pass away, or come to be, or move with any of the other forms of movement;[31] for if it is moved with none of them, it is clear that it is not moved at all. This topic is common for the purposes of both uses—for those of establishing and for those of disestablishing; for if the soul moves with one of the forms of movement, it is clear that it does move, but if it moves with none of these forms, it is clear that it does not move.

If one is not well equipped to attack a thesis, look at it on the basis of the definitions, whether really of the thing proposed or seeming to be so, and, if one is not enough, draw on several. For it will be easier to attack once definitions have been given; for against defined things attack is easier.[32]

In the case of the thing proposed, look to see what if it is so, then the one proposed is so, or what thing is of necessity so, if the thing proposed is so. If one wishes to establish it, look to see what if it is so, then the one proposed will be so (for if the former is proved to be so, the one proposed will also have been proved to be so).[33] On the other hand, if one wishes to disestablish it, look to see what is so if the thing

31. *Ph.* 225b5–9.

32. Reading πρὸς γὰρ τοὺς ὁρισμοὺς ῥᾴων ἡ ἐπιχείρησις.

33. This topic seems to be a case of modus ponens.

proposed is so; for if we prove that what follows from the thing proposed is not so, we will have done away with the one proposed.[34]

Further, look at time to see whether there is any discordance anywhere—for example, if the opponent has said that what is nourished of necessity grows; for animals are nourished all the time, but are not growing all the time. Similarly, if he has said that scientifically knowing is remembering; for the latter is of time past, but the former is also of the present and the future. For we are said to scientifically know present things and future ones (for example, that there will be an eclipse), but it is impossible to remember anything other than what is past.

2.5
A Sophistical Topic and Others

Further there is the sophistical topic,[35] which consists in leading the discussion into the sort of thing against which we are well equipped with lines of attack. Sometimes it will be a necessity, sometimes an apparent necessity, sometimes neither an apparent necessity nor a necessity.

It is a necessity when the answerer has refused to grant one of the things made use of[36] in relation to the thesis, and the questioner makes his arguments against it, and it happens to be of the sort against which he is well equipped with lines of attack. Similarly, it is also a necessity when the questioner, producing an abduction[37] against something due to what is proposed, tries to do away with it; for when it has been done away with, what is proposed is done away with too. It is an apparent necessity, when what the arguments come to proceed against appears to be useful and proper to the thesis, without being so, either when the one who is standing up to the argument has refused to grant it, or when the questioner, from an acceptable abduction based on the thesis, has proceeded with refuting it. The remaining case is when what the arguments come to proceed against is neither a necessity nor an apparent necessity, but, contrary to what should be so, the answerer happens to be refuted on a side issue. One must watch out for the last mode of those stated; for it seems to be wholly far away from and foreign to the craft of dialectic.[38] That is why too the answerer must not lose his temper, but grant things that are not useful against his thesis, but adding a sign when he does not believe one, though he grants it. For questioners for the most

34. This topic seems to be a case of modus tollens.
35. *SE* 172^b25–27.
36. I.e., some premise P that the answerer has made use of because he is defending thesis T, and T commits him to P. Since the questioner is well equipped with lines of attack against P, he can attack T by attacking it.
37. *APr.* 2.25.
38. Because it relies on chance or luck. See *Met.* 981^a3–5, †*MM* 1207^a4–5.

part find themselves more puzzled if, when all premises of this sort have been granted to them, they do not reach a conclusion.

Further, each time a person says anything whatever he in a way says many things, since each thing he says has many necessary consequences—for example, the person who has said that something is a human has also said that it is an animal, animate, two-footed, and receptive of understanding and scientific knowledge, so that by doing away with any one of these consequences whatever, the thing said initially is also done away with. But one must watch out for making a substitution of a more difficult premise; for sometimes a consequence is easier to do away with, but sometimes the thing proposed itself is.

2.6
Additional Topics

As for things to which of necessity only either F or G belongs (for example, to a human either disease or health), if we are well equipped to argue dialectically against one of the two belonging or not belonging, we will be well equipped against the remaining one as well. And this is convertible for both establishing and disestablishing; for if we have proved that one belongs, we will have proved that the remaining one does not belong; but if we prove that the one does not belong, we will have proved that the remaining one does belong. It is clear, then, that this topic is useful for both.

Further, there is attacking by translating a name in accord with its [literal] account,[39] as more fitting to take than the established [equivalent] name—for example, taking "good souled" (*eupsuchos*) not as "courageous" (*andreios*), as now established, but as "having good in one's soul" (*ton eu tên psuchên echonta*), just as "optimistic" (*euelpis*) too is "the one hoping for good things" (*ton agatha elpizonta*). Similarly, *eudaimôn* ("happy") may be taken as "the one whose *daimôn* is excellent"—as Xenocrates calls "happy" the one who has an excellent soul;[40] for the soul is each person's *daimôn*.

Since some things at issue are so of necessity, some for the most part, and some **112^{b}1** however luck may have it, if what is so of necessity is posited as being so for the most part, or what is so for the most part as being so of necessity (either it itself or what is

39. This topic seems to be an outlier—indeed, an odd topic altogether—until we see it in association with, especially, the next one. Suppose, for example, the answerer is defending the thesis that what is *andreios* is not of necessity good. The questioner must first get him to agree, as in accord with established usage he will, that what is *andreios* is of necessity *eupsuchos*. He must then translate *eupsuchos* as literally "having good in one's soul," which is the contrary of the answerer's thesis. Thus the present topic relies on something like the necessity of what is analytic, and so fits in with the other theses in this chapter, all of which have to do with the modal status of theses.

40. F155 Isnardi.

its contrary for the most part), it always provides a topic for the purposes of attack. For if what is so of necessity is posited as being so for the most part, it is clear that the answerer says that F does not belong to all, when it does belong to all, so that he was in error. As he is too if he has stated that what is said to be so for the most part is so of necessity; for then he has stated that it belongs to all, when it does not belong to all. Similarly, if he has stated that the contrary of what is so for the most part is so of necessity; for the contrary of what is so for the most part is always said of things comparatively rarely—for example, if human beings are for the most part base, they are good comparatively rarely. So he was in still greater error, if he has stated that they are of necessity good. It is the same way too if he has stated that what is however luck may have it is so of necessity or for the most part; for what is however luck may have it is so neither of necessity nor for the most part. And even if the opponent has made his statement without distinguishing whether something holds for the most part or of necessity, if in fact the thing at issue is so for the most part, it is possible to argue dialectically as if he had stated it to be so of necessity. For example, if he has stated, without drawing a distinction, that disinherited people are bad, one may argue dialectically as if he had stated it to be so of necessity.

Further, also look to see whether the opponent has posited something as a coincident of itself, on the supposition that it is a distinct thing because it has a distinct name, as Prodicus used to divide pleasures into joy, delight, and merriment; for all these are names of the same thing: pleasure. If, then, someone says that enjoying is a coincident of being merry, he would be saying that it is a coincident of itself.

2.7
Contraries

Since contraries can be combined with each other in six ways, and four of these combinations produce contrariety, one must get hold of contraries in such a way as would be useful both for doing away with things and for establishing them. In any case, it is clear that there are six ways of combining them. For each of the contrary predicates[41] will be combined with each of the contrary subjects, and this in two ways—for example, doing good to friends and doing evil to enemies, or conversely doing evil to friends and doing good to enemies. Or both predicates with one subject, and this also in two ways—for example, doing good to friends and doing evil to friends, or doing good to enemies and doing evil to enemies. Or one predicate with

41. The contraries in the examples are nominalized incomplete sentences ("to do good to friends," "to do evil to enemies") consisting of an infinitive ("to do good," "to do evil") and a noun ("friends," "enemies"), where both the infinitives and the nouns are themselves contraries. In a thesis, the incomplete sentences would be completed: "one must do (or it is choiceworthy to do) good to friends and evil to enemies." See 104a22–26.

both subjects, and this also in two ways—for example, doing good to friends and doing good to enemies, or doing evil to friends and doing evil to enemies.

The first two, then, of the stated combinations do not produce contrariety. For **113ª1**
doing good to friends is not contrary to doing evil to enemies; for both are worthy of choice and belong to the same character. Nor is doing evil to friends contrary to doing good to enemies; for in fact both are worthy of avoidance and belong to the same character. And one thing worthy of avoidance does not seem to be contrary to another, 5
unless the one is said to be so with respect to an excess and the other with respect to a deficiency; for excess seems to be among the things worthy of avoidance as, likewise, does deficiency. The remaining four, however, all produce contrariety. For doing good to friends is contrary to doing evil to friends; for it stems from the contrary character, 10
and the one is worthy of choice, the other of avoidance. It is the same way too in the case of the others; for in each pair, one is worthy of choice, the other of avoidance, and the one belongs to a decent character, the other to a base one.

It is clear, then, from what has been said that the same thing has more than one contrary; for to doing good to friends both doing good to enemies and doing evil 15
to friends are contraries. Similarly, if we look at the others in the same way, it will be evident that each has two contraries. Hence we must take whichever of the two contraries would be useful against the thesis proposed.

Further, if a coincident of a thing has a contrary, look to see whether it belongs to 20
the precise thing to which the coincident has been said to belong; for if the former belongs, the latter could not belong; for it is impossible for two contraries to belong to the same thing at the same time.

Or, if something has been said of something, look to see whether it is such that, if true, contraries must belong to the same thing—for example, if the opponent has said that the Forms are in us; for then it will follow that they are both moving 25
and resting, and further, both perceptible and intelligible. For those who posit the Forms believe that those Forms are at rest and intelligible.[42] But if they are in us, it is impossible for them to be unmoved; for when we move, necessarily everything that is in us moves along with us. And it is clear that they are also perceptible, if indeed 30
they are in us; for it is by means of the perceptual modality of sight that we know the shape [or form] present in each thing.

Again, if a coincident is proposed that has a contrary, look to see whether what is receptive of the contrary is precisely the thing that is also receptive of the coincident; for it is the same thing that is receptive of contraries.[43] For example, if the opponent has said that hatred follows anger, then hatred would be in the spirited part; for that is 35
where anger is. Look to see, then, if its contrary—loving—is also in the spirited part; for if it is not, but is in the appetitive part, hatred could not follow anger. Similarly, if **113ᵇ1**
he has said that the appetitive part is ignorant; for it would be receptive of scientific

42. *Met.* 987ª32–ᵇ8.
43. *Somn.* 453ᵇ27–31, *Met.* 1055ª29–30.

knowledge as well, if indeed it were also receptive of ignorance. But this is precisely what he does not believe, that the appetitive part is receptive of scientific knowledge.

When disestablishing, then, as was said,[44] this must be used. But when establishing that the coincident belongs this topic is not useful—although it is useful for establishing that it is possible for something to belong. For having proved that the thing is not receptive of the contrary, we will have proved that the coincident neither belongs nor can possibly belong. On the other hand, if we prove that the contrary belongs, or that the thing is receptive of the contrary, we will not yet have proved that the coincident also belongs, but rather our proof will have gone only this far: that it is possible that it belongs.

2.8
The Four Sorts of Opposition

Since opposites are of four sorts,[45] in the case of contradictory ones, look to see whether [arguments can be] based on reversing their sequence, both when doing away with things and when establishing them, obtaining it by induction. For example, if what is human is animal, what is not animal is not human. It is the same way in the other cases too. For there their sequence is reversed; for animal follows from human, but not-animal does not follow from not-human, but rather the reverse, not-human from not-animal. One must claim this, then, to be so in all cases—for example, if the noble is pleasant, the not pleasant is also not noble, and if the latter is not so, the former is not so either. Similarly, if the not pleasant is not noble, then the noble is pleasant. Clearly, then, reversing the sequence in the case of contradictories is convertible with an eye to both [establishing and disestablishing].

In the case of contraries, look to see whether contrary follows from contrary, either in the same sequence or in reverse, both when doing away with things and when establishing them, obtaining these too by induction, so far as is useful.[46] The sequence is the same in the case, for example, of courage and cowardice; for virtue follows along with the one and vice the other, and being worthy of choice follows the one and being worthy of avoidance the other. In the latter case again, the sequence is the same; for to being worthy of choice being worthy of avoidance is the contrary. It is the same too in the other cases. On the other hand, the sequence is reversed in such cases as this: health follows the good state, but disease does not follow the bad one, but rather the bad one follows disease. It is clear, then, that in these cases the **114ᵃ1** sequence is reversed. Reversal is rare in the case of contraries; in most of them, the sequence is the same. If, then, the sequence of one contrary and that of the other is neither the same nor reversed, it is clear that neither, in the case of the things stated,

44. 113ᵃ18–19.
45. *Met.* 1018ᵃ20–25.
46. Reading ἐφ᾽ ὅσον χρήσιμον.

does the sequence of one follow along with that of the other. But if in the case of the contraries they do so, then in the case of the things stated as well, it is necessary for that of one to follow along with that of the other.

One must look at cases of privation and having in the same way as contraries, except that in the case of privations there is no reverse. Instead, the sequences are of necessity always in the same direction, just as perception follows along with sight, but non-perception follows along with blindness. For perception is opposed to non-perception as having is to privation; for one of them is a having, and the other a privation.

One must treat cases of relatives in the same way as cases of having and privation;[47] for the sequence of these is in the same direction too. For example, if triple is a multiple, one third is a fraction; for something is said to be a triple relative to a third, and a multiple relative to a fraction. Again, if scientific knowledge is supposition, the scientifically knowable is also supposable; and if sight is a perceptual modality, what is visible is also perceptible. (Objection: There is no necessity, in the case of relatives, for the sequence to occur in the way stated; for the perceptible is scientifically knowable, but perception is not scientific knowledge. And yet the objection does not seem to be true; for many people deny that there is scientific knowledge of perceptible things.[48]) Further, the [topic] mentioned is no less useful for the contrary—for example, that the perceptible is not scientifically knowable; for perception is not scientific knowledge either.

2.9
Co-ordinates and Inflections

Again, look at the case of the co-ordinates and the inflections, both when doing away with things and when establishing them. Things such as the following, for example, are said to be co-ordinates: just things and the just person are co-ordinates of justice, and courageous things and the courageous person are co-ordinates of courage. Similarly, the things that produce something or that protect it are co-ordinates of what they produce or protect—for example, things conducive to health are co-ordinates of health, and things conducive to the good state are co-ordinates of the good state. And the same way in the case of the others. Things of this sort, then, are usually said to be co-ordinates, while things said to be inflections are, for example, justly, courageously, and healthily, and such as are said of things in that way. But inflections also seem to be co-ordinates—for example, justly seems to be a co-ordinate of justice, and courageously of courage. Indeed, all things said in the same column[49] are co-ordinates—for example, justice, just person, just thing, justly. Hence it is clear that when any one

47. Reading τῇ ἕξει καὶ τῇ στερήσει.
48. As Plato is thought to have done. See 113ᵃ27–28.
49. *Met.* 1054ᵇ35–1055ᵃ1, 1058ᵃ13–14.

member, whatever sort it is, that belongs in the same column, is proved to be good
114b1 or praiseworthy, then all the rest also come to be proved so—for example, if justice is something praiseworthy, then a just person, a just thing, and justly done are praiseworthy things. And things done justly will also be said to be done praiseworthily, by the same inflection deriving from praiseworthy as they are said to be justly done by
5 the one deriving from justice.

Look at the contrary not only in the case of the very thing mentioned, but also in the case of its contrary. For example, argue that the good is not necessarily pleasant; for the bad is not necessarily painful either; or that if the latter is the case, so is the former. Also, if justice is scientific knowledge, injustice is also ignorance; and if doing something justly is doing it scientifically and experiencedly, doing it unjustly is doing
10 it ignorantly and inexperiencedly. On the other hand, if the latter are not the case, neither are the former, as in the case of the one stated just now; for doing something unjustly would appear closer to doing it experiencedly than inexperiencedly. This topic was stated previously[50] in connection with the sequences of contraries; for all
15 we are claiming now is that contrary follows along with contrary.

Further, both when doing away with things and when establishing, look at comings to be and passings away, and at what produces things and what destroys them. For those things whose comings to be are good are themselves good, and if they themselves are good, their comings to be are also, but if their comings to be are bad, they themselves are also bad. In the case of passings away, however, it is the reverse;
20 for if the passings away are good, the things themselves are bad, but if the passings away are bad, the things themselves are good. And the same argument applies to what produces things and what destroys them; for things produced by good things are themselves good, but things destroyed by good things are themselves bad.

2.10
Similarity

Again, look at similar things to see whether they hold in a similar way—for example,
25 if one science is of several things, so is one belief; and if to have sight is to see, to have hearing is also to hear. It is the same way in the case of other things too, both in the case of those that are similar and of those that seem so. This topic is useful for both [establishing and disestablishing]; for if something holds in the case of one of the similar things, it also holds of the other similar ones, while if it does not hold in the case
30 of one, it does not hold in the case of the others either. Look to see too whether the thing holds in a similar way in one case as it does in many, since in some cases there is a discordance. For example, if to scientifically know something is to be thinking of it, to scientifically know many things is also to be thinking of many things. But this is

50. 113b27–114a6.

not true; for it is possible to scientifically know many things, but not to be thinking of them. If, then, this is not true, neither is the former, which says that in the case of one thing to scientifically know it is to be thinking of it.

Further, [argue] based on the more and less. There are four topics of the more and less.[51] The first consists in looking to see whether more follows along with more—for example, if pleasure is a good, whether more pleasure is also more good, and if doing injustice is bad, whether doing more injustice is more bad. This topic is useful for **115^{a}1** both [establishing and disestablishing]; for if an increase in the coincident follows along with an increase in the underlying subject, as in the examples stated, it is clear that it coincides with it, while if it does not follow along, it does not coincide. Get hold of this by induction. Another is when one F is said of two things. If F does not belong to the thing to which it is more likely to belong, it does not belong either to the thing to which it is less likely to belong; and if F belongs to the thing to which it is less likely to belong, it also belongs to the thing to which it is more likely to belong. Conversely: when two things (F and G) are said of one thing. If the one (F) that seems to belong to it more does not belong, neither does the one (G) that seems to belong to it less, and if G does belong, F does too. Further: when two things (F and G) are said of two things. If the one (F) that seems to belong more to the one thing does not belong, nor does the remaining one (G) belong to the remaining thing; and if the one that seems to belong less (G) to the one thing does belong, the remaining one (F) also belongs to the remaining thing.

Further, on the basis of F belonging or seeming to belong in a similar degree, [argue] in three ways, as in the case of the more, in the case of the last three topics mentioned. For if F belongs, or seems to belong, in a similar degree to two things, if it does not belong to the one thing, neither does it belong to the remaining thing. Or, if two things (F and G) belong in a similar degree to the same thing, if F does not belong neither does the remaining one (G), while if F does belong, the remaining one (G) does too. It is the same way too if two things (F and G) are said in a similar degree of two things; for if F does not belong to the one, neither does the remaining one (G) belong to the remaining one, while if F does belong to the one, the remaining one (G) does belong to the remaining one.

2.11
Addition and Unconditional versus Conditional Predications

On the basis of the more and less and of similarity, then, it is possible to argue dialectically in these many ways.

Further, it is possible to do so on the basis of addition. If one thing added to another makes it good or white, while the latter was not good or white before, then

51. Reading τοῦ μᾶλλον καὶ ἧττον.

what was added will be good or white—which is also precisely the quality it makes the whole possess. Further, if a thing added to what already possesses a quality makes it be possessed of more of that quality, then the thing itself will also possess it. It is the same way in other cases too. This topic is not useful in all cases, however, but rather in those in which exceeding with respect to more[52] is found to occur. And this topic is not convertible for the purposes of disestablishing. For if what is added does not make the thing good, it is not yet clear whether it itself is not good; for the addition of good to bad does not of necessity make the whole good, nor that of white to black.

Again, if F is said of things more and less, it also unconditionally belongs to them; for things that are not good or white will not be said to be more or less good or white; for a bad thing will never be said to be more or less good but rather more or less bad. This topic too is not convertible for the purposes of disestablishing; for many things that are not said of things more and less[53] do unconditionally belong to them; for someone is not said to be more or less human, but he is not, because of this, not human at all.

In the same way, also look at: in some respect, when, and where; for if a thing is possible in some respect, it is also unconditionally possible. It is the same way with when and where; for what is unconditionally impossible is not possible either in some respect or at some place or time. (Objection: There are people who are in some respect excellent by nature, for example, generous or temperate, who are not unconditionally excellent by nature. Similarly, it is possible for something that admits of passing away not to pass away at a given time, but it is not possible for it unconditionally not to pass away. In the same way too, it is advantageous in some places to follow such-and-such a diet, for example, in pestilential places, but not unconditionally advantageous to follow it. Further, in certain places it is possible for there to be one person, but it is not unconditionally possible for there to be only one person. In the same way too, it is noble in some places to sacrifice one's father, for example, among the Triballi, but it is not unconditionally noble. Or this may signify a relation not to place but to persons; for it makes no difference where they may be; for wherever they are it will be noble for them, since they are Triballi.[54] Again, at certain times it is advantageous to take medicine, for example, when one is sick, but it is not unconditionally so. Or this may signify a relation not to a certain time, but to being in a certain condition; for it makes no difference when he takes it, provided he is in that condition.) What is unconditionally so, however, is what, without any addition, one will say is noble or the contrary—for example, one will not say that it is noble to sacrifice one's father, but rather that for some people it is noble, but not therefore unconditionally noble, while, one will say, with no addition, that to honor the gods is noble; therefore, it is

52. I.e., where, as a result of an addition, the F thing becomes yet more excessively F than before the addition.

53. Reading καὶ ἧττον.

54. Reading οὖσι Τριβαλλοῖς.

unconditionally noble. So whatever, with no addition whatever, seems to be noble or shameful of anything else of that sort, will be said to be unconditionally so.

BOOK 3

116^{a}1

3.1[55]
Relative Choiceworthiness (1)

As for which of two or more things is more choiceworthy or better, look at it on the basis of the following. First, determine that the investigation being made is not into things that are very far apart from each other, or exhibit great difference from each other (for no one raises any puzzles about whether happiness or wealth is more choiceworthy), but into things that are quite close, and about which we dispute as to which we must side with more, because we see no point of superiority of one relative to the other. Clearly, then, in cases of this sort, if one point of superiority can be proved, or more than one, our thought will entirely agree that this is the more choiceworthy, whichever of the two is superior.

First, then, what is longer lasting or more stable is more choiceworthy than what is less so. Also, what the practically wise person or the good man would choose more than other things; or what the correct law would; or people excellent in particular areas, when they make their choice insofar as they are such; or those with scientific knowledge in a given kind,[56] either all of them or most of them—for example, in medicine, or in building, most or all doctors [or builders]; or, in general, what most people, or all of them, or all things would choose—for example, the good; for all things aim at the good. And one must lead the discussion toward whichever of these would be useful. And what is unconditionally better or more choiceworthy is what is in accord with the better science, but what is better or more choiceworthy for a certain thing is what is in accord with the science proper to it.[57]

Next, what is precisely a this something is better or more choiceworthy than what is not in the kind—for example, justice than a just person; for the one is in the kind of the good,[58] while the other is not, and the one is precisely good[59] and the other is not. For nothing is said to be precisely the kind that is not in the kind—for example, pale human is not precisely color. It is the same way in the other cases too.

Also, what is choiceworthy because of itself is more choiceworthy than what is choiceworthy because of something else—for example, being healthy than athletic

55. Many of the topics discussed in these chapters are also discussed in *Rh*. 1.7.
56. Reading ἢ οἱ ἐν ἑκάστῳ γένει ἐπιστήμονες.
57. *Met*. 1026^{a}18–23, 1064^{b}3–6.
58. Reading τῷ ἀγαθῷ.
59. *APo*. 83^{a}24–32.

30 training; for the former is choiceworthy because of itself, the latter because of something else. Also, what is intrinsically choiceworthy is more choiceworthy than what is coincidentally so—for example, that one's friends be just than that one's enemies be just. For the former is intrinsically choiceworthy, the latter coincidentally so; for we coincidentally choose our enemies to be just, in order that they do us no harm. This
35 [topic] is the same as the one before it, with a difference in mode; for we choose that our friends be just because of itself, even if nothing will come to us at all, and even if they may be in India,[60] while we choose that our enemies be so because of something else, that is, in order that they do us no harm.

Also, the intrinsic cause[61] of a good thing is more choiceworthy than its coinci-
116b1 dental cause—for example, virtue than luck (for the former is intrinsically, and the latter coincidentally, a cause of good things), and so with anything else of this sort. Similarly, in the case of the contrary; for what is intrinsically the cause of a bad thing
5 is more to be avoided than what is so coincidentally—for example, vice than luck; for the former is intrinsically the cause, while luck is coincidentally so.

Also, what is unconditionally good is more choiceworthy than what is good for a certain thing or person—for example, becoming healthy than having surgery; for the former is unconditionally good, the latter only for a certain person, the one who needs surgery. Also, what is good by nature is more choiceworthy than what is not
10 good by nature—for example, justice than the just person; for the one is good by nature, while the other's good is something acquired. Also, what belongs to what is better and more estimable is more choiceworthy—for example, to a god than to a human, and to a soul than to a body.

Also, what is special to the better is better than what is special to the worse—for example, to the god than to the human; for with respect to the common ones in both
15 they do not differ at all from each other, but it is in what is special that the one is superior to the other. Also, what resides in better things, prior ones, or more estimable ones is better—for example, health than strength or beauty; for health resides in moist things and dry ones, hot ones and cold ones, and (simply speaking) in all the primary constituents from which a living being is composed, while the others reside
20 in posterior ones. For strength resides in the sinews and bones, while beauty seems to be a sort of symmetry of the limbs.

Also, the end seems to be more choiceworthy than what furthers the end, and of two things that do so, the one that is closer to the end. Also, in general, what furthers the end of life is more choiceworthy that what furthers some other end—for exam-
25 ple, what tends to further happiness than what tends to further practical wisdom. Also, what is possible is more choiceworthy than what is impossible.

Further, of two productive factors, the one whose end is better is more choiceworthy, while of a productive factor and an end, it is based on a proportion: when

60. I.e., too far away to affect us in any way. See *EE* 1226a30–32.
61. *Ph.* 196b25–27.

the superiority of one end over the other is greater than that of the latter over its own productive factor (for example, if happiness is more superior to health than health is to what conduces to health), then what is productive of happiness is superior to health. For what is productive of happiness is as superior to what conduces to health as happiness is to health. But it is assumed that health is less superior to what conduces to health; so what is productive of happiness is more superior to what conduces to health than health is to what conduces to health. It is clear, then, that what is productive of happiness is more choiceworthy than health, since its superiority to the same thing is greater.

Further, what is intrinsically more beautiful, more estimable, and more praiseworthy is more choiceworthy—for example, friendship than wealth, justice than strength; for the former are intrinsically estimable and praiseworthy, while the latter are not intrinsically so, but rather because of something else. For no one honors wealth because of itself, but rather because of something else, but friendship is honored intrinsically, even if nothing else will come to us from it. **117^{a}1**

3.2
Relative Choiceworthiness (2)

Further, when two things are much the same as each other and we cannot see any point of superiority in the one over the other, one must look at them from their consequences. For the one that is followed by the greater good is more choiceworthy; or, if the consequences are bad, the one that is followed by less evil is more choiceworthy; for, though both are choiceworthy, there is nothing to prevent some disagreeable consequence from following. The investigation stemming from things that follow, however, is twofold; for what follows can be either prior or posterior—for example, for the person who learns, being ignorant is prior, being scientifically knowledgeable posterior. For the most part, the posterior consequence is better.[62] One must take, then, whichever of the consequences is useful [dialectically].

Further, a greater number of goods is more choiceworthy than a smaller, either unconditionally or when the one is included in the other, that is, the smaller number in the greater.[63] (Objection: Unless perhaps one is for the sake of the other; for then the two together are not more choiceworthy than the one—for example, becoming healthy plus health than health, since we choose to become healthy for the sake of health. And there is nothing to prevent things that are not [all] good from being more choiceworthy than things that are [all] good—for example, happiness plus another thing that is not good than justice plus courage.) Also, the same things with pleasure

62. I.e., a better good, not better for dialectical purposes.
63. *NE* 1097^{b}15–20, *Rh*. 1363^{b}18–21.

are more choiceworthy than without pleasure. Also, the same things with absence of pain than with pain.

Also, each thing, when its capacity is greater, is at the same time more choiceworthy—for example, absence of pain in old age more than in youth; for its capacity is greater in old age. In line with the same reasoning, practical wisdom is more choiceworthy in old age; for no one chooses young people as leaders, because they do not expect them to be practically wise. With courage, it is the reverse; for it is in youth that activity in accord with courage is most necessary. It is the same way with temperance; for young people are more troubled by their appetites than older ones.

Also, what is more useful at all, or at most, times is more choiceworthy—for example, justice and temperance than courage; for they are always useful, while courage is useful [only] at times.[64] Also, of two things, the one whose possession by all implies that we do not need the other is more choiceworthy than the one whose possession implies that we still need the remaining one in addition, as in the case of justice and courage; for if all were just, courage would be of no use, but if all were courageous, justice would still be useful.

Further, [argue] on the basis of the passings away and losses, the comings to be and acquisitions, and the contraries of things; for things whose passings away are more to be avoided are themselves more choiceworthy. It is the same way in the case of the losses and contraries of things; for a thing whose loss or contrary is more to be avoided is itself more choiceworthy. On the other hand, in the case of comings to be and acquisitions, it is the reverse; for things whose acquisition or coming to be is more choiceworthy are themselves more choiceworthy.

Another topic: What is closer to the good is better and more choiceworthy. Also, what is more similar to the good—for example, justice is better and more choiceworthy than a just person. Also, of two things compared, what is more similar to a better [third one], as Ajax is better than Odysseus, because he is more like Achilles. (Objection that this is not true: For nothing prevents the respects in which Achilles is best from not being the ones in which Ajax is more similar to him, while Odysseus is good though not similar to Achilles. Look to see too whether the similarity is more in the direction of caricature, like the similarity of a monkey to a human being, while a horse is not similar; for the monkey is not more beautiful, though it is more similar to a human.)

Again, of two things, if one is more similar to the better and the other more similar to the worse, the one that is more similar to the better is better. (But this admits of objection too: For nothing prevents one thing from being slightly similar to the better, while the other is strongly similar to the worse—for example, if the similarity of Ajax to Achilles is slight, while that of Odysseus to Nestor is strong. It also admits of objection, if what resembles the better were to resemble it in the direction of the

64. *Pol.* 1334a22–34.

worse, while what resembles the worse does so in the direction of the better, as in the similarity of a horse to a donkey and of a monkey to a human.)

Another [topic]: What is more remarkable is more choiceworthy than what is less so, as is what is more difficult; for we like better having things that are not easy to get. Also, what is more special than what is more commonly shared. Also, what is less commonly shared with bad people.

Further, if this is unconditionally better than that, then the best in this is better than the best in the other—for example, if human is better than horse, the best human is also better than the best horse. Also, if the best in the one is better than the best in the other, then the one is also unconditionally better than the other—for example, if the best human is better than the best horse, then human is unconditionally better than horse.

Further, things that our friends can share are more choiceworthy than those they cannot. Also, things that we would choose to do to a friend more than to a random person are more choiceworthy—for example, doing justice and doing good more than seeming to do them; for we choose to do good to friends more than to seem to do them, while to random people it is the reverse.

Also, what depends on abundance is better than what is necessary, and sometimes also more choiceworthy; for living well is better than living, and living well depends on abundance, while life itself is a necessity. But sometimes what is better is not also more choiceworthy; for it is not the case that if something is better, it is necessarily more choiceworthy; at any rate, to do philosophy is more choiceworthy than to make money,[65] but it is not more choiceworthy for one in need of the necessities. But what depends on abundance is so when, having the necessities, one procures other things that are noble in addition. Roughly speaking, what is necessary is perhaps more choiceworthy, but what depends on abundance is better.

Also, what cannot be procured from another is more choiceworthy than what can also be procured from another, as is the case with justice as compared to courage.[66] Also, if this is choiceworthy without that, but not that without this, [the former is more choiceworthy]—for example, capacity is not choiceworthy without practical wisdom, but practical wisdom is choiceworthy without capacity. Also, if we renounce one of two things in order that the remaining one seems to belong to us, then the one we wish to seem to belong to us is more choiceworthy—for example, we renounce the love of labor in order that we seem to be naturally clever.

Further, what it is less criticizable for people to be annoyed at the absence of is more choiceworthy; also what it is more criticizable for people not to be annoyed at the absence of is more choiceworthy.

65. *NE* 1177^{a}25–26, *Pol.* 1259^{a}16–18.

66. E.g., courageous bodyguards can play many of the roles of one's own courage, but justice is something one must have oneself.

3.3
Relative Choiceworthiness (3)

Further, of things that fall under the same form, the one that has the virtue proper to the form is more choiceworthy than the one that does not have it, and if both have it, the one that has it to a higher degree.

Further, if one thing makes good what it is present in, while another does not, the one that makes it good is more choiceworthy, as too what warms is warmer than what does not. And if both make it good, the one that makes it good to a higher degree, or that makes the better and more controlling thing good, is more choiceworthy—for example, if the one makes the soul good, the other the body.

Further, [determine their relative choiceworthiness] from their inflections, uses, actions, and works, and the latter from the former; for they follow along with each other. For example, if justly done is more choiceworthy than courageously done, justice is more choiceworthy than courage; and if justice is more choiceworthy than courage, justly done is more so than courageously done. And it is much the same way in the other cases too.

Further, if one is a greater and the other a lesser good than the same [third] thing, or if one is greater than a greater good, the greater is more choiceworthy. But, again, if there are two things that are both more choiceworthy than something, the one that is so to a higher degree would be more choiceworthy than the one that is so to a lesser degree. Further, if the excess of one thing is more choiceworthy than the excess of another, the one is more choiceworthy than the other—for example, friendship than wealth; for an excess of friendship is more choiceworthy than an excess of wealth. Also, what a person would wish to be himself the cause of for himself more than that for which [he would wish] someone else [to be the cause] is more choiceworthy—for example, friends than wealth.

Further, [argue] on the basis of an addition, looking to see whether [of two things] added to the same [third] thing, one makes the whole more choiceworthy [than the other]. But one must watch out for proposing a case in which the common thing uses, or in some other way works together with, one of the things added to it, but does not use or work together with the remaining one—for example, a saw or a sickle together with the craft of carpentry; for in their combination the saw is more choiceworthy, but it is not unconditionally more choiceworthy. Again, [one thing is more choiceworthy than another] if, when added to the lesser of two [other] things, it makes the whole greater [than the addition of the other to the greater of them]. Similarly, [one may argue] on the basis of subtraction; for a thing whose subtraction from the same thing makes the remainder a lesser [good than the subtraction of the other] would be greater, whichever one it is whose subtraction makes the remainder a lesser one.

Also, [look to see] whether one thing is choiceworthy because of itself and the other because of the reputation it brings[, since the former is more choiceworthy]—for

example, health than beauty. And the defining mark of reputation is that if no one else knew about it, one would not be eager to have it. Also, it is more choiceworthy if it is so both because of itself and because of its reputation, while the other is so because of only one of the two. Also, whichever is more estimable because of itself is also better and more choiceworthy. A thing would be more estimable because of itself [than another thing] if we would choose it more for its intrinsic self [than that other thing], when we are going to have nothing else because of it.

Further, determine in how many ways things are said to be choiceworthy and for the sake of what—for example, the advantageous, the noble, or the pleasant; for what is useful in furthering all or furthering most of them would be more choiceworthy, provided they are so to a similar degree. And if the same things belong to both, look to see which they belong to more, that is, which is more pleasant, more noble, or more advantageous. Again, what is for the sake of a better thing is more choiceworthy—for example, for the sake of virtue than of pleasure. It is the same way too in the case of things to be avoided; for what more impedes what is choiceworthy is more to be avoided—for example, illness than ugliness; for both to pleasure and to excellence disease is a greater hindrance.

Further, [argue] on the basis of proving that the thing proposed is equally worthy of avoidance and choice. For the sort of thing that one would equally both choose and avoid is less choiceworthy than another that is choiceworthy only.

3.4
Unconditional Choiceworthiness

Comparisons of things with each other must be made, then, in the way stated. But the same topics are also useful for proving that something is [unconditionally] worthy of choice or avoidance; for we need only subtract the excess of one thing over another. For if what is more estimable is more desirable, what is estimable is desirable, and if what is more useful is more choiceworthy, what is useful is choiceworthy, and it is the same way too in the case of other things of the sort that admit of comparison. For in some cases, while comparing one thing with another, we from the outset state too that each of the two things is choiceworthy, or that one of the two is—for example, when we state that the one is good by nature and the other not by nature; for it is clear that what is good by nature is choiceworthy. **119^{a}1**

3.5
More and Greater

The topics concerned with the more and the greater must be taken in their most universal version; for, when so taken, they would be useful for a larger number of

cases. It is possible to make some of the ones mentioned more universal by a slight alteration in their formulation. For example: what is by nature F is more F than what is F not by nature. Also, if one thing makes something that has it, or that it belongs to, F, and another does not, the one that makes it F is more F than the one that does not make it F; and if both make it F, the one that makes it more F.

Further, if one thing is more F and another less F than the same [third] thing, and also, if one thing is more F than a [third] thing that is F, and another is more F than a [fourth] thing that is not F, it is clear that the first is more F. Further, [argue] on the basis of addition, looking to see whether the addition of one to the same thing makes the whole more F [than the addition of the other], or if when added to what is less F, it makes the whole more F. Similarly, [argue] on the basis of subtraction; for a thing whose subtraction makes the remainder less F is itself more F. Also, things that have less of an admixture of the contrary of F are more F—for example, a thing is whiter that has less of an admixture of black.

Further, beyond what was said previously, something that more admits of the account proper to the F proposed [is more F]—for example, if the account of white is "color that dilates sight,"[67] what is more of a color that dilates sight is whiter.

3.6
Particular Predications

If a problem is posed in a particular and not in a universal version, the first universal topics mentioned for establishing or disestablishing are all useful.[68] For when doing away with or establishing something universally, we also prove it in particular; for if it belongs to all, it also belongs to some, and if to none, it does not belong to one either. The topics that are most handy and common are those based on opposites, co-ordinates, and inflections.[69]

For the claim that if all pleasure is good, all pain is also bad, and the claim that if some pleasure is good, some pain is also bad, are similarly acceptable beliefs.[70]
119b1 Further, if some perception is not a capacity, some non-perception is not a lack of capacity. And if something supposable is scientifically knowable, some supposition is scientific knowledge.[71] Again, if some unjustly done thing is good, some unjust thing

67. 107b29–30.
68. The reference could be to the topics in 2.2–3.5, all of which deal with universally quantified problems, even if the quantifier is not always made explicit. The use of *koinoi* ("common") at 119a37, though, seems to further restrict the reference to topics that are not just universally quantified but also common, that is, usable in dealing with a problem regardless of its subject matter. This would limit the relevant topics to those in 2.2–11.
69. 2.9.
70. The opposites are contraries.
71. The opposites are relatives.

is good. Also, if something pleasantly done is to be avoided, some pleasure is to be avoided. In line with the same reasoning, if something pleasant is beneficial, some pleasure is good.

Also, in the case of what destroys, and of comings to be and passings away, it is the same way. For if something that destroys pleasure or scientific knowledge is good, some pleasure or some scientific knowledge would be bad. Similarly, if some passing away of scientific knowledge is good or some coming to be of it is bad, some scientific knowledge will be bad—for example, if someone's forgetting the shameful things he has done is something good, or remembering them something bad, to know scientifically the bad things he has done would be something bad. It is the same too in the other cases; for what is an acceptable belief is similarly so in all of them.

Further, [argue] on the basis of the more and the less and the similar. For if something in another kind is more F [than the thing mentioned in the problem], and nothing in its kind is F at all, the thing mentioned could not be F either—for example, if some science is more of a good than pleasure, while no science is a good at all, pleasure would not be a good either. Also, on the basis of the similar or the less [argue] in the same way; for it will be possible both to do away with things and to establish them, except that, while both are possible on the basis of similarity, on the basis of the less it is possible only to establish things, not to disestablish them. For if some capacity and some science are similarly good, and some capacity is good, some science is good too, and if no capacity is good, no science is either. On the other hand, if some capacity is less good than a science, and some capacity is good, a science is also good. But if no capacity is good, it is not necessary that no science be good either. It is clear, then, that only establishing is possible on the basis of the less.

It is possible to disestablish things not only on the basis of another kind, but also on the basis of the same one, by taking a case that is most of all F—for example, if it is proposed that some science is good, and if it were to be proved that practical wisdom is not good, no other science will be good either, since not even the one that is most of all believed to be good is good. Further, [argue] on the basis of a hypothesis, claiming similarly that if F belongs (or does not belong) to one, it belongs (or does not belong) to all—for example, if the soul of a human is immortal, the other souls are too, but if it is not, neither are the others. If, then, it is proposed that F belongs to some [members of a kind], it must be proved that it does not belong to some; for it will follow because of the hypothesis that it belongs to none at all. But if it is proposed that F does not belong to any, it must be proved that it belongs to some; for it will also follow in this way that it belongs to all. It is clear that the one **120^{a}1** responsible for the hypothesis makes the problem universal, though it was proposed in a particular version; for he claims that one who agrees to it in a particular version must also agree to it in a universal one, since if F belongs to one case, he claims that it belongs to all alike.

When the problem is indeterminate,[72] it is possible to do away with things in only one way—for example, if the opponent has said that some pleasure is good or is not good, and has not made it further determinate in any other way. For if he said that some pleasure is good, it must be proved universally that none is, if the thing proposed is going to be done away with. Similarly, if he said that some pleasure is not good, it must be proved universally that all are. It is not possible to do away with it in any other way; for if we prove that some pleasure is not good or is good, we will not yet have done away with the thing proposed. It is clear, then, that it is possible to do away with a premise of this sort in only one way, but possible to establish it in two ways; for whether we prove universally that all pleasure is good or prove that some pleasure is good, the thing proposed will have been proved. Similarly, when we must argue dialectically that some pleasure is not good, if we prove that no pleasure is good or that some pleasure is not good, we will have argued dialectically in two ways, both universally and in particular, that some pleasure is not good.

If, on the other hand, the thesis is determinate, it will be possible to do away with it in two ways—for example, if it consists in positing that it belongs to some pleasure to be good and does not belong to some pleasure to be good; for whether it is proved that all pleasure is good or that none is good, the thing proposed is done away with. And if what the opponent has posited is that only one single pleasure is good, it is possible to do away with it in three ways; for by proving that all, no, or more than one pleasure is good, we will have done away with the thing proposed. And if the thesis is made still more determinate (for example, if it consists in positing that practical wisdom alone of the virtues is scientific knowledge), it is possible to do away with it in four ways; for if it has been proved that all virtue is scientific knowledge, that none is, that some other virtue (for example, justice) is too, or that practical wisdom itself is not scientific knowledge, the thing proposed will have been done away with.

It is also useful to look at the particular instances, in cases where F has been said to belong or not to belong, just as in the cases of universal problems. Further, one must look among the kinds, dividing them by their forms until one reaches the indivisible ones, as was said previously;[73] for whether F were to appear to belong in all cases or in none, after introducing many instances, one must claim that the opponent must either agree to the universal or bring an objection showing in what case it does not hold. Further, in cases in which it is possible to determine the coincident either by

72. Usually a premise is indeterminate if it has no explicit quantifier (no "all" or "some") (*APr*. 24ª17–22). But that this cannot be the meaning here is shown by the examples of determinate problems at 120ª20–31. The indeterminate problem or premise is "some things are F," which is indeterminate in being refutable in only one way, by proving that all things are not-F (120ª6–10). *Level 1* of determination is some are F and some are not F (120ª20–24), which, as more determinate, is refutable in two ways (120ª21). *Level 2* is only one single thing is F (120ª24–27), which, as more determinate still, is refutable in three ways (120ª25). *Level 3* is only this specific thing is F (120ª27–28), which, as yet more determinate, is refutable in four ways (120ª28).

73. 109ᵇ15–16.

form or by number, look to see whether none of them belongs—arguing, for example, that time is not moved and that it is not a movement either,[74] by enumerating how many forms of movement there are; for if none of these belongs to time, it is **120^{b}1** clear that it is not moved, nor is it a movement. Similarly, [argue] that the soul is not a number by determining that all number is either odd or even; for if the soul is neither odd nor even, it is clear that it is not a number. 5

As regards the coincident, then, one must argue dialectically by means of these and in such a way.

BOOK 4 10

4.1
Kinds, Forms, and Special Affections

Next we must investigate the [topics] related to kind and special affection. These are elements of the topics related to definitions, but the investigations of those practicing dialectic are seldom concerned with these by themselves.

If, then, some kind is proposed for some of the beings, first look at all the beings 15 akin to the one mentioned, to see whether the kind is not predicated of some of them, just as in the case of a coincident.[75] For example, if good is proposed as the kind of pleasure, see whether some pleasure is not good; for if this is so, it is clear that good is not the kind of pleasure; for the kind is predicated of everything falling under the same form. Next, look to see whether it is predicated not in the what-it-is 20 but as a coincident, as white is predicated of snow or self-moved of soul. For snow is not precisely white, which is why white is not the kind of snow, nor is soul precisely what is moving; rather, its being moved is coincidental to it, just as it often is of the animal to walk or to be walking.[76] Further, "moving" does not seem to signify what a 25 thing is but something it does or has done to it. It is the same way with "white"; for it does not indicate what snow is, but rather some quality of it. So neither of them is predicated in the what-it-is, while the kind is predicated in the what-it-is.[77]

Most of all, look at the definition of coincident to see whether it fits the stated 30 kind, as is also the case in the ones just mentioned; for it is possible for a thing to

74. *Ph.* 218^{b}9–20.
75. 109^{b}13–29.
76. Some animals (for example, human beings) have walking as their natural sort of spatial movement. For them to walk is not a coincident, though it is a coincident for them to be walking at any given moment. For other animals (for example, fish) walking is always a coincident, since though they might use their fins (as seals use their flippers) to get around on land, the sort of spatial movement natural to them is swimming, not walking.
77. Reading τὸ δὲ γένος ἐν τῷ τί ἐστι κατηγορεῖται.

move itself[78] and not to do so, and possible, similarly, for it to be white and not to be white. So neither of these is a kind but rather a coincident, since we said[79] that a coincident is what admits of belonging to a subject and of not belonging to it.

Further, look to see whether the kind and form are not in the same division, but rather that the one is substance and the other quality, or the one relative and the other quality. For example, snow and swan are each substance, while white is not substance but quality, so that white is not the kind either of snow or of swan. Again, scientific knowledge is among the relatives,[80] while good and noble are each a quality, so that good, or noble, is not the kind of scientific knowledge; for the kinds of relatives must themselves also be relatives, as in the case of double; for in fact multiple, which is the kind of double, is itself also a relative. To speak in universal terms, the kind must fall under the same division as its form; for if the form is substance, the kind is also, and if the form is quality, the kind is also quality—for example, if white is quality, color is too. It is the same way in the other cases too.

Again, look to see whether it is necessary or possible for the kind to participate in what has been put in the kind. And the definition of participate is "admit of the account of what is participated in." It is clear, then, that the forms participate in the kinds, but not the kinds in the forms; for the form admits of the account of the kind, but not the kind of the account of the form. One must look to see, then, whether the assigned kind participates, or admits of participating, in the form—for example, if someone were to assign something as the kind of being (*to on*) or of one; for it will follow that the kind participates in the form; for being and one are predicated of all beings, so that their account is as well.

Further, look to see whether there is something of which the assigned form is truly predicated although the kind is not—for example, whether what is (*to on*) or what is scientifically knowable is posited as the kind of the believable. For believable will be predicated of what is not (*to mê on*) (for many things that are not are believable), but it is clear that what is and what is scientifically knowable is not predicated of what is not. So neither what is nor what is scientifically knowable is the kind of the believable; for what the form is predicated of, the kind is predicated of as well.

Again, look to see whether what is put in the kind admits of participating in none of its forms; for it is impossible for it to participate in the kind if it participates in none of its forms, unless it just is one of the forms reached at the first division,[81] which do participate in the kind alone. If, then, movement is posited as the kind of pleasure,[82] one must look to see whether pleasure is neither spatial movement nor

78. Reading κινεῖν τι αὐτὸ ἑαυτό.
79. 102ᵇ6–7.
80. *Cat.* 11ᵃ24–32.
81. Unlike at 120ᵇ36, a division here is a division of a kind into forms. If the first division of the kind of animals was into mammals, birds, and fish, each of these would participate in the kind alone, without participating in any of its forms.
82. Plato, *Republic* 583e, *Philebus* 48d.

alteration nor any of the rest of the sorts of movement assigned to things. For then it would be clear that it participated in none of the forms, and so not in the kind either, since it is necessary for what participates in the kind also to participate in some of the forms. So pleasure could not be a form of movement, nor could it be any of the individuals that fall under the form of movement for the beings; for the individuals also participate in the kind and the form—for example, the individual human participates both in human and in animal.

Further, look to see whether the extension of what is put in the kind is wider than that of the kind—for example, as that of what is believable is wider than that of what is; for both what is and what is not are believable, so that what is believable could not be a form of what is; for the extension of the kind is always wider than that of the form. Again, look to see whether the form and the kind have the same extension—for example, if of what follows along with everything, as being and one do, one were posited as form, another as kind; for everything is a being and one, so that neither is the kind of the other, since they have the same extension. It is the same way too if first and starting-point were subordinate one to the other; for the starting-point is first and the first is starting-point, so that either both of the things mentioned are the same or neither is the kind of the other. An element [or topic] relevant to all cases of this sort is that the extension of the kind is wider than that of the form and its difference; for the extension of the difference is also narrower than that of the kind.

See also whether of something, among the things that do not differ in form, the stated kind is not the kind, or does not seem to be the kind—or, if establishing, whether it is the kind of one of them. For the kind of all things that do not differ in form is the same. If, then, it is proved to be the kind of one, it is clear that it is the kind of all, and if not of one, it is clear that it is the kind of none. For example, if someone positing indivisible lines[83] were to say that the indivisible is their kind; for of lines that admit of division, the one mentioned is not the kind, and these do not differ in form from indivisible ones; for all straight lines are no different in form from each other.

4.2
Kinds, Forms, and Differences

Look to see too whether there is any other kind of the assigned form which neither encompasses the assigned kind nor falls under it. For example, if someone were to posit that scientific knowledge is the kind of justice; for virtue is also its kind, and neither of the kinds encompasses the remaining one. So scientific knowledge could not be the kind of justice; for it seems that when one form falls under two kinds,

83. $108^{b}30–31$.

one encompasses the other.[84] But some cases of this sort involve a puzzle; for it seems to some people that practical wisdom is a virtue and also a science, and neither of these kinds is encompassed by the other. Of course, not everyone would concede that practical wisdom is scientific knowledge. If, however, someone were to concede the truth of the affirmation, still for one to fall under the other, or else for both to fall under the same kind, would seem necessary, just as actually happens in the case of virtue and scientific knowledge; for they both fall under the same kind; for each of them is a state and a disposition.[85] Look to see, then, whether neither of these belongs to the assigned kind. For if it is neither the case that one of the kinds falls under the other, or the other under the one, nor that both fall under the same kind, then the assigned one could not be the kind.

Look too at the kind of the assigned kind, and in this way always at the kind above, to see whether they are all predicated of the form, and predicated in the what-it-is; for all the higher kinds[86] must be predicated of the form in the what-it-is. If, then, there is a discordance anywhere, it is clear that what was assigned is not the kind. Again, look to see whether the kind, either itself or one of the higher kinds, participates in the form; for the higher kind participates in none of the lower ones. For disestablishing, then, it must be used in the way stated.

For establishing, on the other hand, if the stated kind is agreed to belong to the form, but that it belongs as kind is disputed, it is enough to prove that one of the higher kinds is predicated of the form in the what-it-is. For if one is predicated in the what-it-is, all of them, both higher and lower ones (if indeed they are predicated), will be predicated in the what-it-is. So the assigned kind too will be predicated in the what-it-is. But the fact that if one kind is predicated in the what-it-is, all the rest as well (if indeed they are predicated) will be predicated in the what-it-is, must be got hold of by induction. But if it is disputed whether the assigned kind belongs at all, it is not enough to prove that one of the higher kinds is predicated in the what-it-is. For example, if someone has assigned spatial movement as the kind of walking, in order to have proved that walking is spatial movement, it is not enough to have proved that it is movement, since there are also other forms of movement. Instead, it must be further proved that walking participates in no other forms in the same division as spatial movement; for what participates in the kind must of necessity also participate in one of the forms in the first division of it. If, then, walking participates neither in increase nor decrease, nor in any of the other forms of movement, it is clear that it would participate in spatial movement, so that spatial movement would be the kind of walking.

84. Aristotle acknowledges that this simple rule of kind subordination may admit of exceptions in certain cases. But that does not mean that it cannot be used in dialectical argument, since the problem under discussion may not be one of those cases. See 122ᵇ1–6.

85. *Cat.* 8ᵇ26–28, *Met.* 1022ᵇ10–11.

86. Reading πάντα γὰρ τὰ ἐπάνω γένη.

Again, in cases in which the posited form is predicated as kind, look to see whether the assigned kind too is predicated in the what-it-is of precisely the things of which the form is predicated, and similarly whether all the kinds higher than this kind are so predicated as well. For if there is a discordance anywhere, it is clear that what is assigned is not the kind; for if it were the kind, all the higher kinds, and it itself, would have been predicated in the what-it-is of precisely the things of which the form too is predicated in the what-it-is. For disestablishing, then, it is useful to see whether the kind is not predicated in the what-it-is of just the things of which the form too is predicated.

For establishing, on the other hand, it is useful to see whether the kind is predicated in the what-it-is. For then it will follow that the kind and the form are predicated in **122^{b}1** the what-it-is of the same thing, so that the same thing falls under two kinds. It is necessary, then, for one of the kinds to fall under the other. If, then, it were proved that the one we wish to establish as kind does not fall under the form, it is clear that the form would fall under it, so that it would have been proved that ours is the kind.

Look also at the accounts of the kinds to see whether they apply both to the assigned form and to the participants in the form; for it is necessary for the accounts of the kinds to be predicated of the form and also of the participants in the form. If, then, there is a discordance anywhere, it is clear that what is assigned is not the kind.

Again, look to see whether the opponent has assigned a difference as kind—for example, immortal as kind of god; for immortal is a difference of living things, since of the living things, some are mortal, others immortal. It is clear, then, that an error has been made; for a difference is not a kind of anything. And that this is true is clear; for no difference signifies a what-it-is but rather a quality, as do "terrestrial" and "two-footed."

Also, look to see whether the opponent has put the difference in the kind—for example, saying that odd is precisely number; for odd is a difference of number, not a form. Neither, it seems, does the difference participate in the kind; for everything that participates in the kind is either a form or an individual, but the difference is neither a form nor an individual. It is clear, then, that the difference does not participate in the kind. So neither could odd be a form, since it does not participate in the kind.

Further, look to see whether the opponent has put the kind into the form—for example, saying that contact is just continuity, or that a mixture is just a blend, or—in accord with Plato's definition[87]—that spatial movement is just movement with respect to place. For contact is not necessarily continuity, but rather the reverse: continuity is necessarily contact; for what is making contact with something is not always conjoined with it, while what is conjoined with something is always making contact with it. It is the same way in the case of the rest as well; for not all mixture is a blend (for a mixture of dry things is not a blend), nor is all movement with respect to place spatial movement; for walking does not seem to be spatial movement; for

87. *Theaetetus* 181d, *Parmenides* 138b–c.

pretty much [only] things that change one place for another non-voluntarily[88]—as happens in the case of inanimate things—are said to be in spatial movement. It is clear too that the extension of the form is wider than that of the kind in the given cases, but it must be the reverse.

Again, look to see whether the opponent has put the difference into the form—for example, saying that what is immortal is precisely god. For it will follow that the form has the same extension or a wider one. But the difference always[89] has the same extension as the form, or a wider one. Further, look to see whether he has put the kind into the difference—for example, saying that color is precisely contracting[90] or number precisely odd. Also, look to see whether he has stated the kind as difference; for it is also possible for someone to introduce a thesis of this sort—for example, making mixture the difference of blend or change of place that of spatial movement. All such cases must be looked at by means of the same procedures; for their topics are interrelated; for the extension of the kind must be wider than that of the difference and must not participate in its difference. But if the kind is assigned as difference, neither of these things can follow; for the extension of the kind will be narrower and the kind will participate in the difference.

Again, if none of the differences belonging to the kind are predicated of the assigned form, the kind will not be predicated of it either—for example, neither odd nor even is predicated of soul, so that number is not predicated of it either. Further, look to see whether the form is prior in nature, and does away with the kind along with itself; for it seems that the contrary is so. Further, look to see whether it is possible for the stated kind, or for its difference, to be absent from the form—for example, for movement to be absent from soul or true and false from belief—for then neither can be its kind or its difference; for the kind and difference seem to follow along with the form, as long as it exists.

4.3
Contraries, Inflections, and Co-ordinates

Look to see too whether what is put in the kind participates in something contrary to the kind, or could possibly participate in it; for then the same thing will participate in contraries at the same time, since the kind is never absent from it, while the thing at issue also participates in what is contrary to the kind, or could possibly participate in it. Further, look to see whether the form shares in something that cannot at all belong to what is in the kind—for example, if the soul shares in life, while no number can possibly be alive, the soul could not be a form of number.

88. Reading σχεδὸν γὰρ ἡ φορὰ ἐπὶ τῶν ἀκουσίως.
89. Reading ἀεὶ δ' ἡ διαφορὰ.
90. 107b29–30.

Look also to see whether the form is homonymous with regard to the kind, using the elements [or topics] already stated for dealing with the homonymous; for the kind and the form are synonymous.

Since of every kind there are several forms, look to see whether it is not possible for there to be another form of the stated kind [besides the assigned one]; for if there is none, it is clear that what is stated could not be a kind at all.

Also, look to see whether the opponent has assigned as the kind what is said of things by means of a metaphor—for example, temperance is harmony; for it is in its literal sense that every kind is predicated of the [several] forms, but harmony is predicated of temperance not in its strict sense but by means of a metaphor; for every harmony consists of notes.

Further, if the form has a contrary, one must look at it. This investigation takes **$123^{b}1$** place in various ways. First of all, look to see whether the contrary is also in the same kind, when the kind has no contrary; for contraries must be in the same kind, if there is no contrary to the kind. On the other hand, if the kind has a contrary, look to see whether the contrary of the form is in the contrary kind; for the contrary form is of necessity in the contrary kind, if indeed the kind has a certain contrary. Each of these points is evident by induction. Again, look to see whether the contrary of the form is not in any kind at all, but is itself a kind—for example, the good; for if this is not in any kind, the contrary of it will not be in any kind either, but will itself be a kind, as happens in the case of the good and the bad; for neither of them is in a kind, but each is itself a kind.

Further, look to see whether both kind and form each has a contrary, and whether there is an intermediate between one pair of contraries but not the other. For if there is an intermediate between the kinds, there is also one between the forms, and if there is one between the forms, there is also one between the kinds, as in the case of virtue and vice, justice and injustice; for each pair has an intermediate. (An objection to this: There is no intermediate between health and disease, though there is one between bad and good.) Or look to see whether, though there is a middle term between both pairs (that is, between the forms and between the kinds), there is not one in the same way, but rather in one case it is by way of negation, while in the other it is as underlying subject. For it is an acceptable belief that it is the same way in both, as in the cases of virtue and vice and justice and injustice; for in both cases the middle terms are by way of negation.

Further, when there is no contrary to the kind, look to see not only whether the contrary is in the same kind, but whether the middle term is too; for it is the kind the extremes are in that the middle terms are also in—as, for example, in the case of white and black; for color is the kind of these and also of all the middle colors. (Objection: Deficiency and excess are in the same kind—for both are in the kind of bad; but the moderate amount, which is intermediate between them, is not in the kind of bad, but in that of good.) Also, look to see whether, while the kind is contrary to something, the form is not contrary to anything. For if the kind is contrary to something, the

form is too, as virtue is the contrary of vice, and justice of injustice.[91] Similarly, if one were to look at the other cases, this would seem evident. (Objection in the case of health and disease: Health is unconditionally the contrary of disease, yet certain disease—for example, fever, eye disease, and each of the others—has no contrary.)

124ᵃ1 When doing away with things, then, investigate in this many ways; for if the stated things do not belong to it, it is clear that what has been assigned is not the kind.

When establishing, on the other hand, one must look in three ways. First of all, look to see whether the contrary [of the form] is in the stated kind, when the kind has no contrary; for if the contrary is in it, it is clear that the one proposed is too. Further, look to see whether the intermediate is in the stated kind; for what the intermediate is in, the extremes are also in. Again, if the kind has a contrary, look to see whether the contrary form is also in the contrary kind; for if it is, clearly the form proposed is in the kind proposed.

Again, in the case of the inflections and co-ordinates [of form and kind], look to see whether they follow along in a similar way, both when doing away with things and when establishing them; for whatever belongs or does not belong to one, at the same time belongs or does not belong to all—for example, if justice is a sort of scientific knowledge, what is done justly is done in a scientifically knowledgeable way and a just person is a scientific knower. But if any of these is not so, none of the rest is either.

4.4
Additional Topics

Again, look at things that bear a similar relation to each other. For example, pleasant bears a similar relation to pleasure as beneficial does to good; for in each case, the one is productive of the other. If, then, pleasure is precisely good, pleasant will also be precisely beneficial; for it is clear that it would be productive of good, since pleasure is good. It is the same way too in the case of comings to be and passings away—for example, if to build is to be active, then to have built is to have been active, and if to learn is to remember, to have learned is to have remembered, and if to be dissolved is to pass away, to have been dissolved is to have passed away, and dissolution is a sort of passing away. And look in the same way at what causes coming to be and what causes passing away, at the capacities and uses of things, and, in general, both when doing away with things and establishing them, look at them in the light of any similarity whatever, as we just stated in the case of coming to be and passing away. For if what causes things to pass away causes them to dissolve, to pass away is to be dissolved; and if what causes things to come to be causes them to be produced, to come to be

91. Reading καθάπερ ἀρετὴ κακίᾳ καὶ δικαιοσύνη ἀδικίᾳ.

is to be produced, and coming to be is production. It is the same way too in the case of capacities and uses; for if a capacity is a disposition, to be capable of something is to be disposed to do it, and if the use of something is an activity, to use is to be active and to have used is to have been active.

If the opposite of a form is a privation, there are two ways to do away with [a claim]. First, look to see whether the opposite is in the assigned kind; for either the privation is unconditionally not anywhere at all in the same kind or not in the ultimate kind—for example, if sight is in perception as its ultimate kind,[92] blindness will not be perception. Second, if a privation is opposed both to the kind and to the form, but the opposite form is not in the opposite kind, neither would the assigned form be in the assigned kind. When doing away with things, then, use the ways as stated. When establishing, on the other hand, there is only one way; for if the opposite form is in the opposite kind, the form would be in the kind proposed—for example, if blindness is a certain sort of non-perception, sight is a certain sort of perception.[93]

Again, look at the denials in reverse order, as was stated in the case of the coincident[94]—for example, if pleasant is precisely good, what is not good is not pleasant; for it is impossible, if indeed good is the kind of pleasant, for anything not good to be pleasant; for what the kind is not predicated of, the form is not predicated of either. Also, when establishing, look in the same way; for if what is not good is not pleasant, what is pleasant is good, so that good is the kind of pleasant.

If the form is a relative, look to see whether the kind is also a relative; for if the form is a relative, the kind is too—for example, double and multiple; for each is a relative. If, on the other hand, the kind is a relative, it is not necessary for the form also to be one; for scientific knowledge is among the relatives,[95] but the craft of grammar is not. (Alternatively, perhaps not even the first thing stated would be believed to be so; for virtue is precisely noble and precisely good, and virtue is among the relatives, but good and noble are not among the relatives, but are qualities.)

Again, look to see whether the form is not said relative to the same thing both intrinsically and with respect to the kind—for example, if double is said of things as double of half, then multiple must be said of things as multiple of half. If it is not, multiple would not be the kind of double.

Further, look to see whether the form is not said relative to the same thing both with respect to the kind and with respect to all of the kinds of the kind. For if double is multiple of half, it will also be said to be "in excess" of the half, and, with respect to all the higher kinds, will unconditionally be said relative to half. (Objection: Something is not necessarily said of things intrinsically and with respect to the kind relative to the same thing; for scientific knowledge is said to be of the scientifically knowable, but a state or disposition is not of the scientifically knowable, but of the soul.)

92. I.e., the highest one.
93. Reading αἴσθησίς τις.
94. $113^{b}15–26$.
95. $121^{a}1$.

Further, look to see whether the kind and form are said in the same way with respect to the inflections—for example, whether to something, of something, or in as many other ways as there are. For as the kind is said of things, so too is the form, as in the case of double and its higher kinds; for both double and multiple are of something. It is the same way too in the case of scientific knowledge; for both scientific knowledge itself and its kinds—for example, disposition and state—are of something. (Objection: In some cases it is not so. For different and contrary are from or to something, but other, which is their kind, is not from or to, but than something; for something is said to be other than something.)

Again, look to see whether the relatives said in accord with the inflections are similar or not similar when converted, as in the case of double and multiple. For each of these is said to be of something, both it itself and in accord with its conversion; for both a half and a fraction are of something. It is the same way too in the case of scientific knowledge and supposition; for these themselves are of something and, when converted, are similar; for both the scientifically knowable and the supposable are so *to* something.[96] If, then, in some cases the conversions are not similar, it is clear that one is not the kind of the other.

Again, look to see whether the form and kind are not said relative to the same number of things. For it seems that both are said in the same way and of the same number of things, as in the case of gift and giving; for a giving is said to be of something to someone, and a gift is of something to someone. And giving is the kind of gift; for a gift is a giving without a giving in return. In some cases, however, the thing is not said relative to the same number of things; for double is double of something, while excess and greater is of something in something; for everything that is in excess (or greater) is always in excess in something and in excess of something. So the things mentioned are not the kinds of double, since they are not said relative to the same number of things. (Alternatively, perhaps it is not universally true that the form and kind are not said relative to the same number of things.)

See too whether the opposite of the kind is the kind of the opposite form—for example, whether, if multiple is the kind of double, fraction is the kind of half; for the opposite of the kind must be the kind of the opposite form. If, then, someone posits that scientific knowledge is precisely perception, the scientifically knowable must also be precisely the perceptible. But it is not; for not everything that is scientifically knowable is perceptible; for in fact some scientifically knowable things are intelligible. So the perceptible is not the kind of the scientifically knowable. And, if this is so, perception is not the kind of scientific knowledge either.

Since of things said as relatives: Some are of necessity in, or have to do with, those things relative to which they happen at any time to be said (for example, disposition, state, and commensurability; for the things just mentioned cannot possibly belong in anything other than the things relative to which they are said). Others, by contrast,

96. *Cat.* $6^{b}34$–35.

do not necessarily belong in those things relative to which they happen at any time to be said, although it is possible (for example, if the soul is said to be scientifically knowable; for there is nothing to prevent the soul from having scientific knowledge of itself, although it is not necessary; for it is possible for this same scientific knowledge to belong in something else). Others cannot possibly belong unconditionally in those things relative to which they happen at any time to be said (for example, **125^{b}1** the contrary in the contrary, or scientific knowledge in the scientifically knowable, unless the scientifically knowable happens to be a soul or a human). Look, then, to see whether the opponent has put something of one sort into a kind that is not of that sort—for example, if he has said that memory is the persistence of scientific knowledge; for all persistence is in what persists and has to do with that, so that the persistence of scientific knowledge too is in the scientific knowledge. Memory, therefore, is in the scientific knowledge, since it is the persistence of scientific knowledge. But this is impossible; for all memory is in the soul.

The topic just stated is common also to the coincident; for it makes no difference whether we say that persistence is the kind of memory or that it is a coincident of it; for if memory is in any way whatever the persistence of scientific knowledge, the same argument will apply to it.

4.5
Additional Topics

Again, look to see whether the opponent has put a state in an activity or an activity in a state—for example, by saying that perception is a movement through the body;[97] for perception is a state, while movement is an activity. Similarly, if he has said that memory is a state that retains a supposition;[98] for no memory is a state, but rather an activity.

People also err who place a state in the capacity that follows along with it—for example, saying that mild-manneredness is the self-control of anger, courage of fears, and justice of profits; for courageous and mild-mannered are said of someone who feels no [anger or fear that needs controlling], while the self-controlled person is the one who feels but is not led by [these]. Perhaps each of these states is indeed followed along with by a capacity of such a sort that, if the person were to feel these feelings, he would not be led by them but rather would control them. But yet this is not what the being for courage is or the being for mild-manneredness, which is rather not to feel such feelings at all.

Sometimes too people posit as kind whatever follows along with [the form]—for example, positing pain as a kind of anger and supposition as a kind of conviction;

97. *Ph*. 244^{b}11–12.
98. *Mem*. 449^{b}24–25.

for while both of the things just mentioned follow along in a way with the assigned forms, neither of them is their kind. For when the person who is feeling anger is pained, the pain has come about in him beforehand; for the anger is not the cause of the pain, but rather the pain of the anger, so that anger is not pain unconditionally.[99] In line with the same reasoning, conviction is not supposition either; for it is possible to have the same supposition without actually being persuaded of it, while this is not possible if indeed conviction is a form of supposition; for it is not possible for a thing to persist as still the same if it is wholly changed in form, just as it is not possible either for the same animal to be at one time a human and at another not. But if someone said that a person who has a supposition is of necessity also persuaded of it, supposition and conviction will have the same extension, so that not even in this way could the one be a kind of the other; for the kind must have a wider extension.

See too whether both naturally occur in the same thing; for what the form occurs in, the kind also occurs in—for example, what white occurs in, color also occurs in, and what the craft of grammar occurs in, scientific knowledge also occurs in. If, then, someone said that shame is fear, or anger pain, it will follow that kind and form do not belong in the same thing; for shame is in the rationally calculative part, while fear is in the spirited one, and pain in the appetitive one (for pleasure is also in it), while anger is in the spirited one.[100] So that what are assigned are not the kinds, since they do not naturally occur in the same thing as the form. Similarly, if love is in the appetitive part, it is not a sort of wish; for all wish is in the rationally calculative part.

This topic too is useful in relation to the coincident; for the coincident and what it is coincident with are in the same thing, so that if they do not appear in the same thing, it is clear that it is not a coincident.

Again, look to see whether the form participates in the proposed kind only in a certain respect; for the kind seems not to be participated in only in a certain respect. For human is not only in a certain respect animal, nor the craft of grammar only in a certain respect science. It is the same way in the other cases too. Look to see, then, whether in some cases the kind is participated in only in a certain respect—for example, if animal is said to be precisely what is perceptible or precisely what is visible. For it is only in a certain respect that animal is perceptible or visible; for in respect of its body it is perceptible and visible, but in respect of its soul it is not. So visible and perceptible could not be the kind of animal.

Without noticing it, people also sometimes put the whole in the part—for example, saying that animal is animate body. But the part is not predicable of the whole at all, so that body cannot be the kind of animal, since it is a part.

See too whether the opponent has put anything that is blameworthy or to be avoided in [the kind of] capacity or the capable—for example, saying that a sophist,

99. 151ᵃ15–17.
100. Cf. *NE* 1128ᵇ10–15.

slanderer, or thief is one who is capable of stealing in secret what is another's;[101] for none of those just mentioned is said to be of the sort that he is because he is capable of one of these things. For both the god and the excellent person are capable of doing base things, but are not of that sort; for the base are all said to be such with respect to their deliberate choice. Further, every capacity is choiceworthy; for even the capacities for base things are worthy of choice, which is why we say that a god and an excellent person have them; for we say that they are capable of doing base things. So capacity cannot be the kind of anything blameworthy; for otherwise it will follow that something blameworthy is worthy of choice; for there will be a certain capacity that is blameworthy. **126^{b}1**

Also, look to see whether he has put anything that is estimable or choiceworthy because of itself in [the kind of] capacity, the capable, or the productive; for every capacity and everything capable or productive is choiceworthy [only] because of something else.

Or look to see whether he has put anything that is in two or more kinds in only one of them; for there are some things that cannot be put in only one kind—for example, the cheat and the slanderer; for neither the one with the deliberate choice to do it but without the capacity, nor the one with the capacity but not the deliberate choice, is a slanderer or a cheat, but rather the one with both. So he must be placed not in one kind, but in both of the kinds just mentioned.

Further, sometimes, reversing the order, people assign the kind as difference or the difference as kind—for example, saying that amazement is the excess of wonder, and conviction is intensity of supposition. For neither excess nor intensity is kind but difference; for amazement seems to be excessive wonder and conviction intense supposition, so that wonder and conviction are kind, while excess and intensity are difference.[102]

Further, if excess and intensity are assigned as kind, inanimate things will be persuaded and amazed; for the intensity and excess of a given thing are present in what they are the intensity and excess of.[103] If, then, amazement is the excess of wonder, amazement will be present in wonder, so that the wonder will be amazed. Similarly, conviction will be present in supposition, if indeed it is intensity of supposition, so that the supposition will be persuaded. Further, assigning things in this way will result in saying that intensity is intense and excess excessive. For there is intense conviction. If, then, conviction is intensity, intensity would be intense. It is the same way there is also excessive amazement. If, then, amazement is excess, excess would be excessive. But neither of these seems to be so, any more than scientific knowledge is a scientifically knowable thing or movement a moving thing.

101. A thief steal's another person's property; a slanderer, another's reputation; a sophist, another person's beliefs or convictions (Plato, *Republic* 413b).

102. Reading ὥστε . . . διαφορά.

103. Reading οὗ ἐστι σφοδρότης καὶ ὑπερβολή.

Sometimes people also err in putting an affection in what has been affected, as its kind—for example, those who say that immortality is eternal life; for immortality seems to be an affection or coincident of life. And that what is said is true would be clear were one to concede that someone could become immortal from having been mortal; for no one will say that he gets a distinct life, but rather that a coincident or affection is added to this same life. So life is not the kind of immortality.

Again, look to see whether they say that an affection is what it is an affection of—for example, saying that wind is moving air. For the same air persists both when moving and when at rest. So wind is not air at all; for otherwise there would be wind even when the air was not moving, if indeed the same air that was wind still persists. It is the same way in other cases of this sort too. Even, then, if one must in this case concede that wind is moving air, nonetheless one must not concede the sort of thing that is assigned with regard to everything of which the kind is not true, but only where the assigned kind is truly predicated. For in some cases—for example, mud and snow—it does not seem to be true. For people say that snow is frozen water and that mud is earth mixed with moisture. But snow is not water, nor is mud earth. So neither of the assigned things could be the kind; for the kind must always be true of every form. Similarly, wine is not fermented water either, in the way that Empedocles speaks of "water fermented in wood";[104] for, unconditionally, wine is not water at all.

4.6
Additional Topics

Further, look to see whether what is assigned is not the kind of anything at all; for clearly it is not then the kind of the form mentioned. Look on the basis of there being no difference in form between the participants of the assigned kind—for example, white things; for these do not differ at all in form from each other, but the forms of all the kinds are different from each other. So white could not be the kind of anything.

Again, look to see whether the opponent has stated as kind or difference something that follows along with everything; for there are several things that follow everything—for example, being and one follow along with everything. If, then, he has assigned being as kind, it is clear that it would be the kind of everything, since it is predicated of them. The kind in fact is not predicated of anything except its forms. So *one* would also be a form of being. It follows, then, that the form too is predicated of everything that the kind is predicated of, since being and one are predicated unconditionally of everything, but the form must be predicated of fewer things. If he has said that what follows everything is a difference, it is clear that the difference will have the same extension as the kind or a wider one; for if the kind too is one of the things

104. B81 DK.

that follow everything, the difference will have the same extension, but if the kind does not follow everything, the difference will have a wider extension than the kind.

Further, look to see whether the assigned kind is said to be in the form as in an underlying subject, as, in the case of snow, white is, so that it is clear that it could not **127ᵇ1**
be the kind; for the kind is only said of the form as underlying subject.[105]

Look to see too whether the kind is not synonymous with the form; for the kind 5
is always predicated synonymously of all the forms.

Further, there is the case where both the kind and the form have a contrary, and your opponent puts the better of the contrary [forms] in the worse kind; for it will follow that the remaining forms will be in the remaining kind, since the contraries are in contrary kinds, so that the better form will be in the worse kind, and the worse 10
in the better; but it seems that the kind of the better is also better. Also, look to see whether, if the same thing is similarly related to both, the opponent has put it in the worse and not in the better kind—for example, saying that the soul is just movement or a thing in movement. For the same soul seems to be similarly capable of rest and 15
capable of movement; so, if rest is better,[106] he should have put soul in this kind.

Further, look on the basis of the more and the less, when disestablishing, to see whether the kind admits of the more, while the form does not do so, neither itself, nor anything said to be what it is in accord with it. For example, if virtue admits of 20
the more, justice and the just person do too; for one person is said to be more just than another. If, then, the assigned kind admits of the more, but the form itself does not do so, and neither does anything said to be what it is in accord with it, the assigned one could not be the kind. 25

Again, if what seems more to be the kind [than what is assigned], or seems equally to be so, is not the kind, it is clear that what is assigned is not the kind either. This topic is useful especially in the sorts of cases where several things appear to be predicable of the form in the what-it-is, no distinction having been drawn between them, nor can we say which of them is kind. For example, both pain and supposition seem 30
to be predicated of anger in the what-it-is, for the angry person both feels pain and supposes he is being treated with contempt. The same investigation is also applicable in the case of the form, by comparing it to another form; for if what seems more or equally to be in the assigned kind is not in the kind, it is clear that the assigned form 35
could not be in the kind either.

When doing away with things, then, use what was just stated. When establishing, on the other hand, the topic of looking to see whether both the assigned kind and the assigned form admit of the more is not useful; for even though both admit of it, **128ª1**
there is nothing to prevent one from not being the kind of the other; for both noble and white admit of it, and neither is a kind of the other. By contrast, the comparison of the kinds and the forms with each other is useful—for example, if this kind and 5

105. *Cat.* 1ª20–29.
106. *NE* 1154ᵇ26–31.

that one equally seem to be kinds, if one is a kind, the other is too. Similarly too, if the one that less seems to be so is a kind, the one that more seems to be so is also—for example, if capacity more seems to be the kind of self-control than virtue does, and virtue is a kind, so is capacity. The same things will be fitting to say also in the case of the form; for if this and that equally seem to be a form of the kind proposed, if one of them is a form of it, the remaining one is as well. And if what less seems to be a form is one, what more seems to be a form is one too.

Further, for the purposes of establishing, look to see whether, of the things of which something has been assigned as kind, it has been predicated in the what-it-is, in the case where not one but several different forms are assigned; for then it is clear that it will be a kind. If, on the other hand, a single form is assigned, look to see whether the kind is predicated of the other forms as well; for then again it will follow that it is predicated of several different ones.

Since it seems to some people that the difference too is predicated of the form in the what-it-is, the kind must be separated from the difference by the use of the elements [or topics] mentioned: first, the kind has a wider extension than the form; further, in assigning the what-it-is it is more fitting to state the kind than the difference (for someone who says that what is human is animal makes the what-it-is more clear than someone who says that it is what is terrestrial); the difference always signifies a quality of the kind, while the kind does not signify a quality of the differences (for someone who says "terrestrial" says "animal of a certain quality," while someone who says "animal" does not say "terrestrial of a certain quality").

This, then, is how the difference must be separated from the kind. Since it seems that if what is musical is, insofar as it is musical, scientifically knowledgeable, music is a sort of scientific knowledge, and if what walks is in movement by walking, walking is a sort of movement—look, in the way just mentioned, at any kind in which one wishes to establish the presence of something. For example, if one wishes to establish that scientific knowledge is precisely conviction, see whether the person who is scientifically knowledgeable, insofar as he knows scientifically, is persuaded; for then it is clear that scientific knowledge would be a sort of conviction. And look in the same way at other cases of this sort too.

Further, since it is difficult to separate what always follows along with a thing and is not convertible with it from what [make it] not be of its kind, if this always follows along with that, but not that with this (as, for example, calm always follows along with absence of wind and divisible with number, but not conversely—for what is divisible is not always a number, nor a calm an absence of wind), one may oneself use as kind of a thing what always accompanies it, when the other is not convertible with it. If, on the other hand, the other person proposes it, one must not grant it in every case. Objection to this: What is not always follows along with what is coming to be (for what is coming to be is not) and is not convertible with it (for what is not is not always coming to be); nonetheless, what is not is not the kind to which coming to be belongs; for what is not simply has no forms.

Concerning the kind, then, inquire in the ways stated.

BOOK 5[107]

5.1
Sorts of Special Affections

To see whether what is stated is a special affection or not, look in the following ways.

A special affection is assigned either intrinsically and always so or in relation to something else and at a time. An example of an intrinsic special affection: a human is "by nature a tame animal"; of one in relation to something else: soul in relation to body (that the one is suited for prescribing and the other for serving); of one that is always so: a god is an "immortal animal"; of one that is so at a time—for example, for a certain human, "walking about in the gymnasium."

What is assigned as a special affection in relation to something else is either two or four problems. For if one assigns this same special affection in relation to one thing and refuses it to another, only two problems arise, as when one assigns "two-footed" as a special affection of the human in relation to the horse. For someone might attack it both by arguing that the human is not two-footed and by arguing that the horse is two-footed. And in both ways the special affection would be undermined. But if, of two affections, one assigns one and refuses the other to each of two things, there will be four problems, as when one assigns to the one "two-footed" and to the other "four-footed" as a special affection of the human in relation to the horse. For it is possible to attack this both by arguing that the human is not two-footed and by arguing that it is naturally four-footed, and also possible to attack it by arguing that the horse is two-footed and by arguing that it is not four-footed. In whatever way it is proved, then, what has been proposed is done away with.

An intrinsic special affection of something is one assigned in relation to everything, and separates it from everything, as, in the case of a human, does "mortal living being receptive of scientific knowledge." One in relation to something else is one that distinguishes a thing not from everything else but from a certain specified thing, as, in the case of virtue in relation to scientific knowledge, does the fact that virtue by nature comes about in more than one place,[108] while scientific knowledge does so only in the rationally calculative part and in those naturally possessing a rationally calculative part. One that is always so is one that is true of its subject at all times and is never absent from it, as, in the case of a living thing, is "composed of soul and body." One that is so at a time is one that is true of its subject at a certain time and does not of necessity always accompany it, as, in the case of a certain human, is "walking about in the marketplace."

107. The authenticity and placing of this book have been doubted, but it seems to be referred to as coming after discussion of kinds in Book 4 at $120^{b}11$–12 and $139^{b}4$–5.
108. *NE* $1144^{b}3$–$1145^{a}2$.

To assign a special affection in relation to something else is to state a difference that holds either in all cases and always, or for the most part and in most cases. For example, in all cases and always: in the way that it is a special affection of the human in relation to horse that it is "two-footed"; for human is always and in every case two-footed, while no horse at any time is two-footed. For the most part and in most cases: in the way that it is a special affection of the rationally calculative part in relation to the appetitive part and to the spirited part that it prescribes and the other serves; for the rationally calculative part does not always prescribe, sometimes it is also prescribed to, and the appetitive part and the spirited part[109] are not always prescribed to either, but sometimes—when the soul of a human being is depraved—also prescribe.

Among the special affections, the most logico-linguistic are the ones that are so intrinsically and always and the ones that are so in relation to something else. For a special affection that is so in relation to something else is several problems, as we also said previously;[110] for the problems that arise are of necessity either two or four. Hence the arguments that arise in regard to these are several. The one that is intrinsically so and the one that is always so may be attacked in relation to many things or looked out for in relation to several times. The one that is intrinsically so can be attacked in relation to many things (for it is in relation to each of the beings that the special affection of a particular being must belong to it, so that if this being is not separated by it in relation to all of them, the special affection could not have been correctly assigned); the one that is so always can be looked out for in relation to many times; for if it does not belong, did not belong, or is not going to belong, it will not be a special affection.[111] On the other hand, the one that is so at a time we look at in relation to the now-said time.[112] There are not, then, many arguments with regard to it. But a logico-linguistic problem is one with regard to which it is possible for arguments that are both many and good to arise.

What has been said to be a special affection in relation to something else, then, must be looked at on the basis of the topics dealing with the coincident, to see whether it is coincident with one thing and not coincident with another. But on those that are so always and on those that are intrinsic, one must look at by means of the following [topics].

109. Reading καὶ θυμικὸν here and at 129ª14.

110. 128ᵇ22–23.

111. Reading παρατηρεῖν, as at 129ª23.

112. Suppose A says now that it is a special affection of B to be walking about in the gymnasium. The time he says it is both the time of B's walking (the time that is now when he says it) and the time at which its truth value is to be determined.

5.2
The Correct Assignment of a Special Affection (1)

First, look to see whether the special affection has been incorrectly or correctly assigned. To see whether it is incorrectly or correctly assigned, one [topic] is to see **$129^{b}1$** whether the special affection is proposed through things that are not better known or through things that are better known—when disestablishing, see whether they are not proposed through things that are better known; when establishing, whether they are proposed through things that are better known.[113]

To prove that it is assigned through things that are not better known, one way is to look to see whether the special affection one assigns is wholly more unknown 5 than the subject whose special affection one has stated it to be; for then the special affection will not have been correctly proposed. For it is for the sake of knowledge that we render the special affection.[114] The subject must, then, be separated by means of things that are better known; for this way it will be possible to understand it more adequately. For example, since a person who has posited "most similar to soul" as a special affection of fire makes use of soul, which is more unknown than fire (for 10 we know more what fire is than soul), "most similar to soul" would not be correctly proposed as a special affection of fire.

Another way is to look to see whether this special affection is not better known as belonging to this subject. For not only must this special affection be better known than the thing in question, but also it must be better known as belonging to this subject; for a person who does not know whether this one belongs to this thing will 15 also not know whether it belongs to it alone, so that, whichever of the two situations occurs, the special affection comes to lack perspicuousness. For example, since a person who has posited "what soul is naturally found primarily in" as a special affection of fire has made use of something more unknown than fire, namely, whether soul is found in fire and whether it is found primarily in it, "what soul is naturally found primarily in" would not be correctly proposed as a special affection of fire. 20

When establishing, on the other hand, look to see whether the special affection is proposed through things that are better known, and whether the "better known" holds in each of the two ways.[115] For then the special affection will in this respect have been correctly proposed; for of the topics useful for establishing that a special affection is correctly proposed, some will prove that in this respect only it is correctly proposed, others that it is unconditionally correctly assigned. For example, since a 25 person who has stated "possessing perception" as a special affection of animal has assigned it through things that are better known, in accord with each of the two ways,

113. *Ph.* $184^{a}16$–18, *Met.* $1029^{b}3$–5.
114. $130^{a}4$–5, $131^{a}1$.
115. Better known than its subject and better known to belong to it.

"possessing perception" would in this respect have been correctly assigned as a special affection of animal.

Next, when disestablishing, look to see whether any of the names assigned in [the account of] the special affection is said of things in many ways, or whether too the account as a whole signifies several things; for then the special affection will not have been correctly proposed. For example, since "to perceive" signifies several things, to have perception and to be using perception, "to naturally perceive" would not be correctly proposed as a special affection of animal. Because of this, neither a name nor an account said of things in several ways must be used in signifying a special affection, because what is said of things in many ways makes what is said lack perspicuousness, puzzling the person about to attack it as to which of the several things being said one means; for a special affection is assigned for the sake of learning. Further, in addition to this, it is necessary for those who assign a special affection in this way to submit to a sort of refutation, when someone produces a deduction in the case of one of the many ways in which the thing is said where there is a discordance.[116]

When establishing, on the other hand, look to see whether all the names and also the account as a whole do not signify several things; for the special affection will then in this respect be correctly proposed. For example, since "body" does not indicate many things and neither does "what is most easily moved upward" or the whole composed by putting these together, "the body that is most easily moved upward" would be correctly proposed in this respect as a special affection of fire.

Next, when disestablishing, look to see whether what the special affection is assigned to is said of things in many ways, but it is not made determinate in which of them one is positing it as a special affection; for then the special affection will not have been correctly assigned. The cause due to which this is so is not unclear from what was said previously;[117] for the same things necessarily follow. For example, since "the scientific knowledge of this" signifies many things (for it signifies its having scientific knowledge, its using scientific knowledge, having scientific knowledge of it, and using the scientific knowledge of it), a special affection of "the scientific knowledge of this" would not be correctly assigned, without its having been made determinate of which of them one is positing it as a special affection.

When establishing, on the other hand, look to see whether the thing one posits the special affection of is not said of things in many ways, but is rather one and simple; for then the special affection will in this respect be correctly proposed. For example, since human is said of things in one way, "animal tame by nature" would be correctly proposed in this respect as a special affection in the case of human.

Next, when disestablishing, look to see whether the same thing has been said several times in the special affection; for often, without its being noticed, people do this in special affections too, just as they also do in definitions. And a special affection to

116. 111ᵇ24, 114ᵇ32.
117. 129ᵇ30–130ᵃ14.

which this has happened will not be correctly proposed; for what is said many times confuses the listener. Thus it necessarily becomes non-perspicuous, and in addition the proposers seem to babble.[118] Saying the same thing several times will happen in two ways: one is when someone has used the same name several times—as would happen if someone were to assign "the body that is the lightest of bodies" as a special affection of fire (for he has said body several times); second, if he were to assign accounts in place of names—as would happen if he were to assign "the substance that of all bodies is, in accord with nature, most spatially moved downward" as a special affection of earth, and were then to put "substances of such-and-such sort" in place of "bodies," since body and substance of such-and-such sort are one and the same; for in this way "substance" will be said several times. So neither of these special affections would have been correctly proposed.

When establishing, on the other hand, look to see whether one is not using the same name several times; for then the special affection would in this respect have been correctly assigned. For example, since a person who has stated "animal receptive of scientific knowledge" as a special affection of human has not used the same name several times, the special affection of human would in this respect have been correctly assigned.

Next, when disestablishing, look to see whether the opponent has assigned in the special affection anything of the sort that belongs to everything. For what does not separate the subject from certain things will be useless, while what is said in special affections must separate it, just as what is said in definitions also must. Hence the special affection will not be correctly proposed. For example, since a person who has posited as a special affection of scientific knowledge, "supposition that is incapable of being persuaded to change by argument, since it is one,"[119] has used something in the special affection—the "one"—that belongs to everything, the special affection of scientific knowledge would not have been correctly proposed.

When establishing, on the other hand, look to see whether one has used not something common, but something that separates the subject from something; for then the special affection will in this respect be correctly proposed. For example, since a person who has stated "possessing a soul" as a special affection of living thing has used nothing common, "possessing a soul" would in this respect have been correctly proposed as a special affection of living thing.

Next, when disestablishing, look to see whether the opponent has assigned several special affections to the same thing, without determining that he is positing several; for then the special affection will not be correctly proposed. For just as in definitions nothing more must be proposed beyond the account that indicates the substance, so too in special affections nothing must be assigned beyond the account that makes

118. *SE* 165^{b}15–17, 173^{a}31–^{b}16, 181^{b}25–182^{a}6.

119. Reading ἓν ὄν. "One" is presumable to be understood as meaning "tightly unified." See *APo*. 72^{a}37–^{b}4.

what is stated the special affection; for something of that sort is useless. For example, since a person who has stated "the most fine-grained and lightest body" as a special affection of fire has assigned several special affections (for each of the two is truly stated of fire alone), "the most fine-grained and lightest body" would not have been correctly proposed as a special affection of fire.

When establishing, on the other hand, look to see whether one has not assigned several special affections to the same thing, but rather only one; for then the special affection will be in this respect correctly proposed. For example, since a person who has stated "body that is brought to assume any shape" as a special affection of liquid has assigned one thing and not several as its special affection, the special affection of liquid would in this respect have been correctly proposed.

5.3
The Correct Assignment of a Special Affection (2)

Next, when disestablishing, look to see whether the opponent has made additional use either of the subject itself whose special affection one is assigning, or something belonging to it; for then the special affection will not be correctly proposed. For a special affection is assigned for the sake of learning.[120] The subject, on the other hand, is as unknowable as itself, while anything belonging to it is posterior to it, and hence no better known than it is, so that through these we cannot learn anything more.[121] For example, since a person who has stated "substance of which human being is a form" as a special affection of living thing has made additional use of something belonging to it, the special affection would not have been correctly proposed.

When establishing, on the other hand, look to see whether one is not using either the subject itself or anything belonging to it; for then the special affection will in this respect be correctly proposed. For example, since a person who has posited "composed of soul and body" as a special affection of living thing has not made use of the thing itself or anything belonging to it, the special affection of living thing would in this respect have been correctly assigned.

In the same way, look in the case of other things that do not make the subject better known. When disestablishing, look to see whether the opponent has made additional use of anything that is either opposite to the subject or, in general, anything simultaneous in nature with it or posterior to it; for then the special affection

120. 129ᵇ7–8.

121. Suppose A is a special affection of B, and the opponent makes use of B in proposing A. Then A will not teach us about B, because we must already know B in order to understand A. Suppose that instead of using B itself in proposing A, the opponent uses X, which is a form of B. Then the definition of X will include B, and so A will again not teach us anything new about B.

will not be correctly proposed.[122] For the opposite of a thing is simultaneous by nature with it, and what is simultaneous by nature with a thing and what is posterior to it do not make it better known. For example, since a person who has stated "most opposed to bad" as a special affection of good has made additional use of the opposite of good, the special affection would not have been correctly assigned.

When establishing, on the other hand, look to see whether one has not made additional use of anything that is either opposite to the subject or, in general, simultaneous in nature with it, or posterior to it; for then the special affection will in this respect have been correctly assigned. For example, since a person who has posited "most persuasive supposition" as a special affection of scientific knowledge has not made additional use of anything either opposite to, simultaneous in nature with, or posterior to the subject, the special affection of scientific knowledge would in this respect have been correctly proposed.

Next, when disestablishing, look to see whether the opponent has not assigned as a special affection something that does not always accompany the subject but rather something that sometimes ceases to be a special affection; for then the special affection will not be correctly stated. For the name of the subject is not of necessity true of what we find the special affection to belong to, nor is the name of the subject of necessity not applied to what we find the special affection does not to belong to, so that the special affection would not have been in this respect correctly proposed. Further, in addition to this, even when he has assigned the special affection, it will not be evident that it belongs, if indeed it is the sort of thing that may be absent.[123] The special affection, then, will not be perspicuous. For example, since a person who has posited "moving" as a special affection of living thing has assigned the sort of special affection that is sometimes not a special affection, the special affection would not have been correctly proposed.

When establishing, on the other hand, look to see whether one has assigned what of necessity is always a special affection; for then the special affection will in this respect be correctly proposed. For example, since a person who has posited "what **131b1** makes its possessor excellent" as a special affection of virtue has assigned as a special affection what always accompanies its subject, the special affection of virtue would have been in this respect correctly assigned.

Next, when disestablishing, look to see whether in assigning a now-special affection, the opponent has not made it determinate that it is a now-special affection that he is assigning; for then the special affection will not be correctly proposed. For, first, anything beyond what is customary always needs to be made additionally determinate, and people are for the most part accustomed to assigning as a special affection what always accompanies the subject. Second, a person is unclear who has not made it determinate whether it is a now-special affection that he wished to posit,

122. *Cat.* 14b27–15a7.
123. 131b19–36.

and one must not give any pretext for critical investigation. For example, since a person who has posited "sitting with a certain someone" as a special affection of a certain human being posits a now-special affection, the special affection would not have been correctly assigned, if indeed he stated it without making this determinate.

When establishing, on the other hand, look to see whether in assigning a now-special affection one has posited it making it determinate that one is positing a now-special affection; for then the special affection will in this respect be correctly proposed. For example, since a person who has stated "walking about now" as a special affection of a certain human being has made this determinate in his statement, the special affection would be correctly proposed.

Next, when disestablishing, look to see whether the special affection[124] the opponent has assigned is of the sort whose belonging is not evident except to perception; for then the special affection will not be correctly proposed. For every perceptible thing becomes unclear when outside the range of perception; for it is not evident whether it still belongs, because this is known only by perception. And this will be true in the case of any affections that do not always and of necessity follow along with the subject. For example, since a person who has posited "the brightest star spatially moving above the earth" as a special affection of the sun has used in the special affection "spatially moving above the earth" a sort of thing that is known only by perception, the special affection of the sun would not have been correctly assigned; for it will be unclear, when the sun sets, whether it is spatially moving above the earth, because the perception is then absent from us.

When establishing, on the other hand, look to see whether the special affection one has assigned is of the sort that is not evident to perception, or, if it is perceptible, clearly belongs of necessity to the subject; for then the special affection will in this respect be correctly proposed. For example, since a person who has posited "the primary thing that is colored" as a special affection of surface has made use of something perceptible ("colored"), but this is of a sort that manifestly always belongs to it, the special affection of surface would in this respect have been correctly assigned.

Next, when disestablishing, look to see whether the opponent has assigned the definition as special affection; for then the special affection will not be correctly proposed; for a special affection must not indicate the essence.[125] For example, since a person who has stated "terrestrial two-footed animal" as a special affection of human has assigned what signifies its essence as a special affection of human, the special affection of human would not have been correctly assigned.

When establishing, on the other hand, look to see whether the special affection one has assigned is counterpredicated with the subject but does not indicate the essence; for then the special affection will in this respect have been correctly assigned. For example, since a person who has posited "by nature a tame animal" as a special

124. Reading τὸ ἴδιον.
125. 102ᵃ18–19.

affection of human has assigned as special affection something that is counterpredicated of the subject but does not indicate its essence, the special affection of human would in this respect have been correctly assigned.

Next, when disestablishing, look to see whether the opponent has assigned the special affection but has not put [the subject] in its what-it-is. For in special affections, just as in definitions, the first thing to be assigned must be the kind, and then the rest must be attached immediately afterward and must make the separation.[126] So a special affection that is not proposed in this way would not have been correctly assigned. For example, since a person who has stated "having a soul" as a special affection of living thing has not put the living thing in its what-it-is, the special affection of living thing would not have been correctly proposed.

When establishing, on the other hand, look to see whether one has put the subject, whose special affection one is assigning, in its what-it-is, and then attaches the rest; for then the special affection will in this respect have been correctly assigned. For example, since a person who has posited "animal receptive of scientific knowledge" as a special affection of human has put the subject kind in its what-it-is and then assigned the special affection, the special affection of human would, in this respect, have been correctly proposed.

5.4
Whether an Affection Assigned as Special Is in Fact Special (1)

To see whether the special affection has been correctly assigned, then, look by means of these [topics]. But one must look at whether what is stated is a special affection, or not a special affection at all, on the basis of the following ones. For the topics that simply establish that the special affection is correctly proposed will be the same as those that make it a special affection at all, and thus will be stated in connection with these.

First, then, when disestablishing, take a look at each subject of which the opponent has assigned the special affection, to see, that is, whether it belongs to none of them, or whether it is not true of them in the relevant respect; for then what is proposed as being a special affection will not be a special affection. For example, since "not being deceivable by argument" is not true of the geometer (for he could be deceived when a false diagram is drawn[127]), "not being deceivable by argument" would not be a special affection of the scientific knower.

When establishing, on the other hand, look to see whether the special affection is true of every case and true in the relevant respect; for then what is proposed as

126. In Greek the natural order in the definition of human is *zô[i]on pezon dipoun* (animal, terrestrial, two-footed), while in English the natural order is two-footed terrestrial animal, so that the kind comes last.
127. *SE* 171[b]12–16.

not being a special affection will be a special affection. For example, since "animal
132b1 receptive of scientific knowledge" is true of every human, and true of him insofar as he is human, "animal receptive of scientific knowledge" would be a special affection of human. {This topic, when disestablishing, goes this way: look to see whether the account is not true of what the name is true of, and whether the name is not true of what the account is true of; when establishing, on the other hand: look to see whether
5 the account too is predicated of what the name is predicated of, and whether the name too is predicated of what the account is predicated of.}[128]

Next, when disestablishing, look to see whether the account is not said of what the name is said of, and whether the name is not said of what the account is said of;
10 for then what was proposed as being a special affection will not be a special affection. For example, since "living thing that shares in scientific knowledge" is true of the god, but "human" is not predicated of the god, "living thing that shares in scientific knowledge" would not be a special affection of human.

When establishing, on the other hand, look to see whether the name too is predicated of what the account is predicated of, and whether the account too is predicated of what the name is predicated of; for then what is proposed as not being a special
15 affection will be a special affection. For example, since "living thing" is true of "what has a soul" is true of, and "having a soul" is true of what "living thing" is true of, "having a soul" would be a special affection of living thing.

Next, when disestablishing, look to see whether the opponent has assigned the underlying subject as a special affection of what is said to be in[129] the underlying
20 subject; for then what is proposed as a special affection will not be a special affection. For example, since a person who proposes "fire" as a special affection of the body having the finest-grained particles has assigned the underlying subject as a special affection of what is predicated of it, "fire" would not be a special affection of the body having the finest-grained particles. That is why the underlying subject will not be a special affection of what is in the underlying subject, because the same thing will
25 then be a special affection of several things that differ in form. For several things that differ in form belong to the same thing, which are said of it alone, and of all of these the underlying subject will be a special affection, if one posits the special affection in this way.

When establishing, on the other hand, look to see whether one has assigned what is in the underlying subject as a special affection of the subject; for then what is proposed as not a special affection will be a special affection, if indeed it is predicated
30 only of it in the way that a special affection is said. For example, since a person who has stated as a special affection of earth "body heaviest in form" has assigned as a special affection of the underlying subject what is said of that thing alone and in the

128. Secluded as an abridged variant of the topic that follows.

129. Here, unlike at 127b1, "in" does not have its technical meaning, but simply means "predicated of."

way that a special affection is predicated, the special affection of earth would have been correctly proposed.

Next, when disestablishing, look to see whether the opponent has assigned the special affection by virtue of participation; for then what is proposed as a special affection will not be a special affection. For what belongs by virtue of participation[130] contributes to the essence, and, as such, would be a difference said of some one form. For example, since a person who has stated "two-footed terrestrial" as a special affection of human has assigned the special affection as something by virtue of participation, "two-footed terrestrial" would not be a special affection of human.

When establishing, on the other hand, look to see whether one has not assigned the special affection as something by virtue of participation, nor as indicating the essence, though the thing is counterpredicated of it; for then what is proposed as not being a special affection will be a special affection. For example, since a person who has posited "naturally having perception" as a special affection of animal has assigned the special affection neither by virtue of participation nor as indicating the being, though the thing is counterpredicated of it, "naturally having perception" would be a special affection of animal.

Next, when disestablishing, look to see whether the special affection admits of not belonging at the same time as the name, but rather admits of belonging posterior or prior to it; for then what is proposed as a special affection will not be a special affection—either not ever, or not always. For example, since "walking through the marketplace" admits of belonging to someone both prior and posterior to "human," "walking through the marketplace" would not be a special affection of the human—either not ever, or not always.[131]

When establishing, on the other hand, look to see whether the special affection of necessity always belongs at the same time, without being either a definition or a difference; for then what is proposed as not being a special affection will be a special affection. For example, since of necessity "animal receptive of scientific knowledge" always belongs at the same time as "human" does, and is neither a difference nor a definition, "animal receptive of scientific knowledge" would be a special affection of human.

Next, when disestablishing, look to see whether the same thing is not a special affection of the same things, insofar as they are the same; for then what is proposed as being a special affection will not be a special affection. For example, since "appearing good to certain people" is not a special affection of the worthy of pursuit, neither would "appearing good to certain people" be a special affection of the choiceworthy; for the worthy of pursuit and the worthy of choice are the same.

130. 121^{a}11–12.

131. The human is human prior to walking in the marketplace, and posterior to having walked in it.

When establishing, on the other hand, look to see whether the same thing is a special affection of something that is the same thing [as the subject], insofar as it is the same; for then what is proposed as not a special affection will be a special affection. For example, since "having a tripartite soul" is said to be a special affection of human, insofar as it is human, it would also be a special affection of mortal, insofar as it is mortal, to have a tripartite soul.[132] This topic is also useful in the case of the coincident; for to the same things, insofar as they are the same, the same ones must belong, or not belong.

Next, when disestablishing, look to see whether the special affection of things that are the same in form is not always the same in form; for then the proposed special affection will not be a special affection of the stated subject either. For example, since horse and human are the same in form,[133] and it is not always a special affection of a horse "to stand still of its own accord," it would not always be a special affection of a human "to move of its own accord"; for moving of its own accord and standing still of its own accord are the same in form, each of them occurring to an animal insofar as it is animal.

When establishing, on the other hand, look to see whether the special affection of things that are the same in form are always the same in form; for then what is proposed as not being a special affection will be a special affection. For example, since it is a special affection of human to be "two-footed terrestrial," it would also be a special affection of bird to be "two-footed flyer"; for each of these is the same in form, the one lot, insofar as they are forms falling under the same kind, since they fall under animal, and the other lot, insofar as they are differences of the kind "animal." This topic is false when one of the special affections mentioned belongs to one certain form only, while the other belongs to many—for example, "four-footed terrestrial."

Since same and distinct are said of things in many ways, it takes work, faced with someone who takes things in a sophistical way, to assign a special affection of some one thing and of it alone; for what belongs to something that has something as a coincident will also belong to the coincident taken together with the thing it is a coincident of. For example, what belongs to human will also belong to pale human, if human is pale, and what then belongs to pale human will also belong to human. One might, then, attack many special affections by making the underlying subject one thing when taken intrinsically and a distinct thing when taken together with a coincident of it—for example, saying that human is one thing and pale human a distinct thing. And further, by making the state and what is said in accord with the state distinct. For what belongs to the state also belongs to what is said with respect to the state, and what belongs to what is said with respect to the state belongs to the state too. For example, since a scientific knower is said to be in a certain state with respect to scientific knowledge, "incapable of being persuaded to change by

132. Plato, *Republic* 435c–441c.

133. Because there is a form (sub-kind) of living thing—animal—to which they both belong.

argument" would not be a special affection of scientific knowledge; for then the scientific knower too will be incapable of being persuaded to change by argument.

When establishing, on the other hand, one must say that the thing a coincident belongs to is not unconditionally distinct from the coincident taken together with the thing it is a coincident of, but is said to be distinct from it because the being for each of them is distinct; for the being for human is not for a human the same thing as being for pale human is for a pale human. Further, one should look at the inflections and say that the scientific knower will not be *what* is incapable of being persuaded to change by argument, but *who* is incapable of being persuaded to change by argument, and that scientific knowledge is not *what* is incapable of being persuaded to change by argument but *which* is incapable of being persuaded to change by argument; for against the person who offers every sort of objection, one must put up every sort of resistance.[134]

5.5
Whether an Affection Assigned as Special Is in Fact Special (2)

Next, when disestablishing, look to see whether, while wishing to assign [as a special affection] what belongs by nature, the opponent posits it by his speech in such a way as to signify what always belongs; for then the proposed special affection would seem to be undermined. For example, since a person who has stated two-footed as a special affection of human wishes to assign what belongs by nature, but signifies by his speech one that belongs always, two-footed would not be a special affection of human; for not every human has two feet.

When establishing, on the other hand, look to see whether one wishes to assign as a special affection what belongs by nature, and by one's speech signifies it this way; for then the special affection will not in this respect be undermined. For example, since a person who assigns "animal receptive of scientific knowledge" as a special affection of human both wishes and by his speech signifies, the [sort of] special affection that belongs by nature, "animal receptive of scientific knowledge" would not in this respect be undermined as not being a special affection of human.

Further, it takes work to assign the special affection of whatever sorts of things are said to be so primarily with respect to something else or as themselves primarily so; for if one has assigned a special affection as belonging to what is so with respect to something else, it will also be true of what is primarily so; but if you have posited it as belonging to what is primarily so, it will also be predicated of what is so with respect to something else. For example, if one has assigned "colored" as a special affection of surface, "colored" will also be true with respect to body, while if one has assigned it

134. *What*, *who*, and *which* correspond to different inflections of the definite article in Greek, agreeing with subjects of different genders. The scientific knower is masculine (*ho*); scientific knowledge, feminine (*hê*); what is incapable of being persuaded, neuter (*to*).

as a special affection of body, it will also be predicated of surface. So it will not hold that what the account is true of, the name will also be true of.

In the case of some special affections, it for the most part happens that a certain error occurs from not determining how and of which things the special affection is posited. For everyone tries to assign as the special affection what belongs by nature (as to human, "two-footed" does); what actually belongs (as to a certain human, "having four fingers" does); what belongs to the form (as to fire, "having the finest-grained particles" does); what belongs unconditionally (as to animal, "living" does); what belongs with respect to something else (as to soul, "practically wise" does); what belongs primarily (as to the rationally calculative part, "practically wise" does); what belongs because of the subject having a certain thing (as to the scientific knower, "incapable of being persuaded to change by argument" does—for it will be because of nothing other than having a certain thing that he is incapable of being persuaded to change by argument); what belongs because the subject is had by a certain thing (as to scientific knowledge, "incapable of being persuaded to change by argument" does); what belongs because the subject is participated in by something (as to animal, "perception" does—for something else, such as human, also perceives, but because animal already participated [in it]); or what belongs because the subject participates in something (as to a certain animal, "living" does).

Someone errs, then, if he does not add "by nature," because what belongs by nature admits of not actually belonging to what it belongs to by nature (as to human, "having two feet" does). —Also if he does not determine that he is assigning what actually belongs, because it will not be such as to belong to that subject, like "having four fingers" to human. —Also if he has not made clear that he is positing it as primarily so or as so with respect to something else, because then it will not hold that what the account is true of, the name will also be true of (as is the case with "colored," whether assigned as a special affection of surface or of body). —Also, if he has not stated beforehand that he has assigned the special affection either because of the subject having a thing, or because of a certain thing having the subject, because then it will not be a special affection; for if he assigns it because of a certain thing having the subject, it will belong to what has the thing, while if he assigns it because of what has the thing, it will belong to the thing that is had (as "incapable of being persuaded to change by argument" belongs when posited as a special affection of scientific knowledge and of the scientific knower). —Also if he has not, in addition, signified that he assigns it because of the subject participating in something or because of it being participated in by something, because then the special affection will belong to certain other things as well; for if he assigns it because of the subject being participated in by something, it will belong to the participants, and if he assigns it because of its participating in something, it will belong to the things participated in (as is the case if one has posited "living" as a special affection of a certain animal and of animal). —Also if he has not explicitly distinguished the special affection as belonging to the form, because then it will belong to only one of the things that fall

under what he is positing the special affection of; for the superlative degree belongs to only one of them (as to fire, "lightest" does). Sometimes, though, one has erred even if one has added "to the form." For the things mentioned will have to be of one form when "to the form" is added. But in some cases this does not happen (as it does not in the case of fire; for there is not only one form of fire; for glowing ember, flame, and light are distinct in form, though each of them is fire).

It is because of this that, when "in form" is added, there must not be a form other than the one mentioned: because the special affection stated will belong to some things more and to others less (as in the case of fire "having the finest-grained particles" does; for light consists of finer-grained particles than ember-glow or flame does). And this should not happen unless the name too is predicated more of what the account is more true of (otherwise it will not be the case that what the account applies to more, the name also applies to more). Further, in addition to this, the same thing will be the special affection both of the unconditionally so and of the most so **135^{a}1** in respect of what is this unconditionally (as "having the finest-grained particles" is in the case of fire; for this same thing will also be a special affection of light; for it is light that has the finest-grained particles). If, therefore, someone else assigns the special affection in this way, one must attack it. But for oneself, one must not give an opening for this objection, but in positing the special affection one must immediately determine in what way one is positing the special affection.

Next, when disestablishing, look to see whether the opponent has posited a thing as a special affection of itself; for then what is proposed as being a special affection will not be a special affection. For a thing itself always indicates the being of it; and what indicates the being is not a special affection but a definition. For example, since a person who has stated "appropriate" as a special affection of noble has assigned the thing as a special affection of itself (for the noble and the appropriate are the same thing), appropriate would not be a special affection of noble.

When establishing, on the other hand, look to see whether, though one has not assigned the thing itself as a special affection of itself, one has posited as a special affection something counterpredicated; for then what has been proposed as not being a special affection will be a special affection. For example, since a person who has posited "animate substance" as a special affection of animal has not posited the thing itself as a special affection of itself, but has assigned something counterpredicated, "animate substance" would be a special affection of animal.

Next, in the case of uniform things, look to see, when disestablishing, whether the special affection of the whole is not true of the parts, or if that of a part is not said of the whole; for then what is proposed as being a special affection will not be a special affection. In some cases it happens that this occurs; for in the case of uniform things, someone might assign a special affection, sometimes looking to the whole, and sometimes giving his attention to what is said of the parts. And in neither case will the special affection be assigned correctly. For example, in the case of the whole, since a person who has stated "the greatest quantity of salt water" as a special affection

of sea has posited the special affection of something uniform, but has assigned one of such a sort as is not true of the part (for a certain sea is not the greatest quantity of salt water), "the greatest quantity of salt water" would not be a special affection of sea. In the case of the parts, for example, since a person who has posited "breathable" as a special affection of air has stated the special affection of something uniform, but has assigned one of such a sort as is true of certain air, but is not said of the whole (for the whole air is not breathable), "breathable" would not be a special affection of air.

When establishing, on the other hand, look to see whether, while it is true of each part of the uniform things, it is a special affection of them as a whole; for then what is proposed as not being a special affection will be a special affection. For example, since "by nature spatially moved downward" is true of all earth, but this is a special affection of a certain [piece of earth] by virtue of earth, "by nature spatially moved downward" would be a special affection of earth.

5.6
Opposites

Next, one must look on the basis of opposites.

First, look on the basis of contraries. When disestablishing, do so to see whether the contrary of what is proposed is not a special affection of the contrary [subject]; for then neither will the contrary be a special affection of the contrary [subject]. For example, since injustice is contrary to justice, and the worst evil to the best good, but it is not a special affection of justice to be "the best good," it would not be a special affection of injustice to be "the worst evil."

When establishing, on the other hand, look to see whether the contrary is a special affection of the contrary; for then the contrary to the first will also be a special affection of the contrary to the second. For example, since bad is contrary to good, and the worthy of avoidance to the worthy of choice, and "worthy of choice" is a special affection of good, "worthy of avoidance" would be a special affection of bad.

Second, look on the basis of relatives. When disestablishing, do so to see whether the relative [to what is proposed] is not a special affection of the relative [to the subject]; for then neither will the relative [to the subject] be a special affection of the relative [to what is proposed]. For example, since double is said of things relative to half, and exceeding to being exceeded, and "exceeding" is not a special affection of double, "being exceeded" would not be a special affection of half.

When establishing, on the other hand, look to see whether the relative [to what is proposed] is a special affection of the relative [to the subject]; for then the relative [to the subject] will also be a special affection of the relative to [what is proposed]. For example, since double is said of things relative to half, and two-to-one relative to one-to-two, and it is a special affection of two to be "as two-to-one," it would be a special affection of half to be "as one-to-two."

Third, when disestablishing, look to see whether what is said as a having is not a special affection of the having; for then neither will what is said as a privation be a special affection of the privation. Also, if what is said as a privation is not a special affection of the privation; for then neither will what is said as a having be a special affection of the having. For example, since being "the absence of perception" is not said to be a special affection of deafness, neither would being "the presence of perception" be a special affection of hearing.

When establishing, on the other hand, look to see whether what is said as a having is a special affection of the having. For then what is said as a privation will be a special affection of the privation. Also, if what is said as a privation is a special affection of the privation, what is said as a having will also be a special affection of the having. For example, since "to see" is a special affection of sight, in as much as we have sight, it would be a special affection of blindness "not to see," in as much as we do not have the sight it is natural for us to have.

Next, look on the basis of positive and negative terms.

First, on the basis of the predicates themselves. This topic is useful only when disestablishing. For example, see whether the positive predicate or what is said in terms of the positive predicate is a special affection of the subject; for then neither the negative one nor what is said in terms of the negative one will be a special affection of the subject. Also, if the negative one or what is said in terms of the negative one is a special affection of the subject, neither the positive one nor what is said in terms of the positive one will be a special affection of the subject. For example, since "animate" is a special affection of living thing, "not-animate" would not be a special affection of living thing.

Second, look on the basis of the predicates, positive or negative, and on the basis of the subjects they are affirmed or denied of. When disestablishing, do so to see whether the positive predicate is not a special affection of the positive subject; for then neither will the negative be a special affection of the negative. Also, if the negative predicate is not a special affection of the negative subject, neither will the positive be one of the positive. For example, since "animal" is not a special affection of human, neither would "non-animal" be a special affection of non-human. Also, if "non-animal" appears not to be a special affection of non-human, neither will "animal" [appear to] be a special affection of human.

When establishing, on the other hand, look to see whether the positive predicate is a special affection of the positive subject; for then the negative will also be a special affection of the negative. Also, if the negative predicate is a special affection of the negative subject, the positive will also be a special affection of the positive. For example, since "not-living" is a special affection of non-animal, "living" would be a special affection of animal. Also, if "living" appears to be a special affection of animal, "not-living" will appear to be a special affection of non-animal.

Third, look on the basis of the underlying subjects themselves. When disestablishing, do so to see whether the special affection assigned is a special affection of

the positive subject; for then the same thing will not also be a special affection of the negative subject. Also, if the special affection assigned is a special affection of the negative subject, it will not be a special affection of the positive subject. For example, since "animate" is a special affection of living thing, "animate" would not be a special affection of not-living thing.

When establishing, on the other hand, look to see whether the special affection assigned is not a special affection of the positive subject; for then it would be one of the negative subject. But this topic is false; for a positive predicate is not a special affection of a negative subject, nor a negative one of a positive one. For a positive predicate does not belong to a negative subject at all, whereas a negative predicate, while it does belong to a positive subject, does not belong as a special affection.

Next, look on the basis of the co-ordinate members of a division. When disestablishing, do so to see whether none of the co-ordinate members in the division is a special affection of any of the remaining members; for then neither will what is proposed be a special affection of what it is proposed as a special affection of. For example, since "perceptible living thing" is not a special affection of any of the other living things, "intelligible living thing" could not be a special affection of a god.

When establishing, on the other hand, look to see whether any of the remaining co-ordinate members of the division whatever is a special affection of each of these co-ordinate members; for then the remaining one will also be a special affection of what it has been proposed as not being a special affection of. For example, since it is a special affection of practical wisdom to be "intrinsically and naturally a virtue of the rationally calculative part," then, if each of the other virtues is taken in this way, it would be a special affection of temperance to be "intrinsically and naturally a virtue of the appetitive part."

5.7
Inflections and Similarity of Relations

Next, look on the basis of the inflections. When disestablishing, do so by seeing whether one inflection [of the predicate] is not a special affection of the corresponding inflection [of the subject]; for then neither will another inflection of it be a special affection of the corresponding inflection. For example, since "nobly" is not a special affection of justly, neither would "noble" be a special affection of just.

When establishing, on the other hand, look to see whether one inflection [of the predicate] is a special affection of the corresponding inflection [of the subject]; for then another inflection of it will also be a special affection of the corresponding inflection. For example, since "two-footed terrestrial" is a special affection of human,

it would be a special affection of the *by* a human to be said to be "*by* a two-footed terrestrial."[135]

Look at the inflections not only of the actual thing mentioned but also of its opposites, as was said in the case of the earlier topics as well.[136] When disestablishing, do so by seeing whether one inflection of one opposite is not a special affection of the corresponding inflection of the other opposite; for then neither will another inflection of the one be a special affection of the corresponding inflection of the other. For example, since "well" is not a special affection of justly, neither would "badly" be a special affection of unjustly.

When establishing, on the other hand, look to see whether one inflection of one opposite is a special affection of the corresponding inflection of the other opposite; for then another inflection of the one opposite will also be a special affection of the corresponding inflection of the other opposite. For example, since "best" is a special affection of the good, "worst" will also be a special affection of the bad.[137]

Next, look on the basis of similarity relations. When disestablishing, do so by seeing whether one thing that has a similarity relation to one thing is not a special affection of a second thing that has a corresponding similarity relation to a second thing; for then neither will it be a special affection of the first thing to have the relevant similarity relation to the first thing. For example, since the builder has a relation to producing a house that is similar to the one the doctor has to producing health, and it is not a special affection of the doctor to "produce health," it would not be a special affection of the builder to "produce a house."

When establishing, on the other hand, look to see whether one thing that has **137^a1** a similarity relation to one thing is a special affection of a second thing that has a corresponding similarity relation to a second thing; for then it will also be a special affection of the first thing to have the relevant similarity relation to the first thing. For example, since a doctor has a relation to being productive of health that is similar to the one the athletic trainer has to being productive of a good condition, and it is a special affection of the athletic trainer to be "productive of a good condition," it would be a special affection of the doctor to be "productive of health."

Next, look on the basis of things that have the same relations. When disestablishing, do so to see whether what has the same relation [to something] is not a special affection of it when it has the same relation [to something else]; for then neither will it be a special affection [of the first thing] to have the same relation [to the first thing]. If, on the other hand, it is a special affection [of the second thing], it will not be a special affection of what it is proposed as being a special affection of. For example,

135. The inflected forms here are datives.

136. Perhaps a reference to the topics on inflections at 114^b6–15, but more likely to those on opposites in 5.6, especially the ones on contraries (135^b7–16).

137. The lack of a morphological connection between *beltistos* (best) and *agathos* (good), *cheiristos* (worst) and *kakos* (bad), shows—and is perhaps intended to show—that inflections are not to be thought of syntactically, but semantically and also, presumably, ontologically.

since practical wisdom has the same relation to the noble and to the shameful (for it is the scientific knowledge of each of them), and it is not a special affection of practical wisdom to be "the scientific knowledge of the noble," it would not be a special affection of practical wisdom to be "the scientific knowledge of the shameful." But if it is a special affection of practical wisdom to be "the scientific knowledge of the noble," it would not be a special affection of it to be "the scientific knowledge of the shameful";[138] for it is impossible for the same thing be a special affection of several things.[139]

When establishing something, on the other hand, this topic is of no use; for what has the same relation is one thing brought into combination with several things.

Next, when disestablishing, look to see whether the predicate that is said with respect to being is not a special affection of the subject that is said with respect to being; for then neither will the predicate that is said with respect to ceasing to be, be a special affection of the subject that is said with respect to ceasing to be, nor will the predicate that is said with respect to be coming to be, be a special affection of the subject that is said with respect to coming to be. For example, since "animal" is not a special affection of human, neither would "coming to be animal" be a special affection of coming to be human, nor would "ceasing to be animal" be a special affection of ceasing to be human. In the same way, precisely as it now has been said from being to coming to be and to ceasing to be, one must also get from coming to be to being and ceasing to be, and from ceasing to be to being and coming to be.

When establishing, on the other hand, look to see whether the predicate assigned with respect to being is a special affection of the subject assigned with respect to being; for then the predicate that is said with respect to coming to be will also be a special affection of the subject said with respect to coming to be, and the predicate with respect to ceasing to be will be a special affection of the subject that is said with respect to ceasing to be. For example, since "mortal" is a special affection of human, "coming to be mortal" would be a special affection of the coming to be human, and "ceasing to be mortal" of the ceasing to be human. In the same way, one must also get from coming to be and ceasing to be to being, and to these from these, as one was told to do when disestablishing.

Next, take a look at the [Platonic] Form of what is proposed. When disestablishing, do so to see whether the special affection does not belong to the Form, or not with respect to that which it was said to be by the person who proposed it as the special affection; for then what was proposed as being a special affection will not be a special affection. For example, since "at rest" does not belong to human-itself,[140]

138. Reading οἷον ἐπεὶ . . . εἶναι αἰσχροῦ.

139. The thought seems to be that whatever makes "scientific knowledge of the noble" *alone* a special affection of practical wisdom cannot also make "scientific knowledge of the shameful" *alone* a special affection of it, since practical wisdom stands in the same relation to the noble and the shameful.

140. I.e., the Platonic Form of human. See *Met.* 1040b27–34.

insofar as it is human, but rather insofar as it is a Form, "at rest" would not be a special affection of human.

When establishing, on the other hand, look to see whether the special affection belongs to the Form, and belongs to it with respect to that which it was said to be insofar as what was proposed is not a special affection of it. For then what was proposed as not being a special affection will be a special affection. For example, since it belongs to animal-itself to be "composed of soul and body," and belongs to it insofar as it is animal, "composed of soul and body" would be a special affection of animal.

5.8
The More and the Less and Similarity of Degree

Next, look on the basis of the more and the less.

First, when disestablishing, do so to see whether the more so is not a special affection of the more so; for then neither will the less so be a special affection of the less so, nor the least so of the least so, nor the most so of the most so, nor the unconditionally so of the unconditionally so. For example, since "more colored" is not a special affection of what is more a body, neither would "less colored" be a special affection of what is less a body, nor would "colored" be one of body at all.

When establishing, on the other hand, look to see whether the more so is a special affection of the more so; for then the less so will also be a special affection of the less so, the least so of the least so, the most so of the most so, and the unconditionally so of the unconditionally so. For example, since "more perceiving" is a special affection of the more living, and "less perceiving" would be a special affection of the less living, and "most so," then, of the most so, and "least so" of the least so, and "unconditionally so" of the unconditionally so.

Also, look on the basis of the unconditionally so toward those same things. When disestablishing, do so to see whether "unconditionally so" is not a special affection of the unconditionally so; for then neither will "more so" be a special affection of the more so, nor "less so" of the less so, nor "most so" of the most so, nor "least so" of the least so. For example, since "excellent" is not a special affection of human, neither is "more excellent" a special affection of the more human.

When establishing, on the other hand, look to see whether "unconditionally so" is a special affection of the unconditionally so; for then "more so" will be a special affection of the more so, "less so" of the less so, "least so" of the least so, and "most so" of the most so. For example, since "moving spatially upward in accord with nature" is a special affection of fire, "moving more spatially upward in accord with nature" would be a special affection of what is more fire.[141] In the same way, look at all these on the basis of the others. **138a1**

141. 146a13–18.

Second, when disestablishing, look to see whether the "more" is not a special affection; for then neither will the "less" be a special affection. For example, since "perceiving" is more a special affection of living thing than "scientifically knowing" is of human, and "perceiving" is not a special affection of living thing, "scientifically knowing" would not be a special affection of human.

When establishing, on the other hand, look to see whether the "less" is a special affection; for then the "more" will also be a special affection. For example, since to be by nature "tame" is less a special affection of human than "living" is of animal, and it is a special affection of human to be "tame by nature," "living" would be a special affection of animal.

Third, when disestablishing, look to see whether the special affection [proposed] is not a special affection of what it is more a special affection of; for then neither will it be a special affection of what it is less a special affection of; but if it is a special affection of the first, it will not be a special affection of the second. For example, since "colored" is more a special affection of surface than of body, and it is not a special affection of surface, "colored" would not be a special affection of body, while if it is a special affection of surface, it would not be a special affection of body.

When establishing, on the other hand, this topic is not useful; for it is not possible for the same thing to be a special affection of several things.

Fourth, when disestablishing, look to see whether what is more a special affection of a given subject is not a special affection of it; for then neither will what is less a special affection of it be a special affection of it. For example, since "perceptible" is more a special affection of animal than "divisible"[142] is, and "perceptible" is not a special affection of animal, neither would "divisible" be a special affection of animal.

When establishing, on the other hand, look to see whether what is less a special affection of a given subject is a special affection of it; for then what is more a special affection of it will be a special affection. For example, since "perceiving" is less a special affection of animal than "living" is, and "perceiving" is a special affection of animal, "living" would be a special affection of animal.[143]

Next, look on the basis of special affections that belong in a similar way. First, when disestablishing, to see whether what is a special affection in a similar degree is not a special affection of that of which it is a special affection in a similar degree; for then neither will what is a special affection in a similar degree be a special affection of that of which it is a special affection in a similar degree. For example, since "appetitive desiring" is a special affection of the appetitive part[144] in a degree similar to that in which "rational calculating" is a special affection of the rationally calculative part, and "appetitive desiring" is not a special affection of the appetitive

142. *DA* 411[b]19–21.

143. Animals are always living, but not always perceiving.

144. The appetitive part is not always appetitively desiring.

part, neither would "rationally calculating" be a special affection of the rationally calculating part.

When establishing, on the other hand, look to see whether what is a special affection in a similar degree is a special affection of that of which it is a special affection in a similar degree; for then what is a special affection in a similar degree will also be a special affection of that of which it is a special affection in a similar degree. For example, since "the primary locus of practical wisdom" is a special affection of the rationally calculative part in a degree similar to that in which "the primary locus of temperance" is a special affection of the appetitive part, and "the primary locus of practical wisdom" is a special affection of the rationally calculative part, "the primary locus of temperance" would be a special affection of the appetitive part.

Second, when disestablishing, look to see whether what is in a similar degree a special affection of a given subject is not a special affection of it; for then neither will what is in a similar degree a special affection be a special affection of it. For example, since it is in a similar degree that "seeing" and "hearing" are special affections of human, and "seeing" is not a special affection of human, neither would "hearing" be a special affection of human.

When establishing, on the other hand, look to see whether what is in a similar degree a special affection of it is a special affection of it; for then what is in a similar degree a special affection of it will be a special affection of it. For example, since "appetitive due to a part of itself being primarily so" is in a similar degree a special affection of soul as "rationally calculative due to a part of itself being primarily so," and it is a special affection of soul to be "appetitive due to a part of itself being primarily so," it would be a special affection of soul to be "rationally calculative due to a part of itself being primarily so."

Third, when disestablishing, look to see whether it is not a special affection of what it is in a similar degree a special affection of; for then neither will it be a special affection of what it is in a similar degree a special affection of; while if it is a special affection of the first, it will not be a special affection of the second. For example, since "to burn" is to a similar degree a special affection of flame and glowing ember, and "to burn" is not a special affection of flame, "to burn" would not be a special affection of glowing ember, while if it is a special affection of flame, it would not be a special affection of glowing ember.

When establishing, on the other hand, this topic is not at all useful.

The topic based on similarity relations[145] differs from the one based on special affections that belong in a similar degree, because the former is got hold of by analogy, not by looking at the belonging of some affection, while the latter is based on what belongs being brought into combination with other things.

145. $136^{b}33$–$137^{a}7$, $138^{a}30$–$^{b}22$.

5.9
Capacities and Superlatives

Next, when disestablishing, look to see whether, in assigning the special affection as a capacity, the opponent has not assigned the special affection also as a capacity in relation to what is not, when the capacity does not admit of belonging to what is not; for then what is proposed as being a special affection will not be a special affection. For example, since a person who has stated "breathable" as a special affection of air has, on the one hand, assigned the special affection as a capacity (for the breathable is the sort of thing that can be breathed), and, on the other hand, has assigned the special affection also in relation to what is not (for air in fact admits of being even though no animal is of a sort to naturally breathe the air; yet if no animal is, nothing can breathe; so neither will it be a special affection of air to be "the sort of thing that can be breathed at a time when there is no animal of the sort that can breathe it")—[since all that is so,] it would not be a special affection of air to be "breathable."

When establishing, on the other hand, look to see whether in assigning the special affection as a capacity, one assigns the special affection either as a capacity in relation to what is or—when the capacity admits of belonging to what is not—in relation to what is not; for then what is proposed as not being a special affection will be a special affection. For example, since a person[146] who assigns "capable of being affected or of affecting" as a special affection of what is assigns the special affection as a capacity, and has assigned the special affection in relation to what is (for when what is, is, it will be capable of being affected or of affecting in some way), so that "capable of being affected or of affecting" would be a special affection of what is.

Next, when disestablishing, look to see whether the opponent has posited the special affection as a superlative; for then what is proposed as being a special affection will not be a special affection. For the result for those who assign the special affection in this way is that what the name is true of, the account is not true of; for when the thing has passed away, nonetheless the account will be [true of something]; for it will belong most of all to things that are. For example, if someone were to assign "the lightest body" as a special affection of fire; for if fire has passed away, there will still be some body that is the lightest. So "the lightest body" would not be a special affection of fire.

When establishing, on the other hand, look to see whether one has not posited the special affection as a superlative; for then the special affection will in this respect be correctly proposed. For example, since a person who has posited "by nature a tame animal" as a special affection of human has not assigned the special affection as a superlative, the special affection would in this respect be correctly proposed.

146. Plato, *Sophist* 247e.

BOOK 6

6.1
Definitions

Where definitions are concerned, the study has five parts; for one must prove that it is not true at all to apply the account also to what the name applies to (for the definition of human must be true of every human); that though the subject to be defined has a kind, the opponent has not put it in the kind, or has not put it in its proper kind (for the definer must put the subject in the kind and then attach the differences; for of the things in the definition the kind seems most of all to signify the substance of the thing defined); that the account is not special (for the definition must be special, as was said previously[147]); that, though having done all the things mentioned, he has not given a definition, that is, not stated the essence of the thing defined. And beyond the things mentioned it remains to see whether, though he has given a definition, he has not given it correctly.

Whether, then, the account is not also true of what the name is true of, should be looked at on the basis of the topics related to the coincident;[148] for there too the looking is always to see whether it is true or not true [of the thing]. For when we argue dialectically that a coincident belongs, we say that it is true, and when it does not belong, that it is not true. If the opponent has not put the subject in its proper kind, however, or if the assigned account is not special to the subject, one must look at it on the basis of the topics related to the kind and the special affection.[149]

It remains to state how one must proceed to say whether the thing has either not been defined or not defined correctly. First, then, one must look to see whether it has not been defined correctly. For it is easier to do anything whatever than to do it correctly. It is clear, then, that error is more frequent where the latter is concerned, since it is more arduous work. So attack is easier where it is concerned than where the former is concerned.

Not defining correctly has two parts. One consists in doing so by using an expression that is not perspicuous (for the definer must use the most perspicuous expression possible, since it is for the sake of making the thing known that the definition is being assigned). The second is if he has stated the account in a more extended version than is necessary; for any additional component in the definition is superfluous. And each of the ones mentioned is again divided into several parts.

147. 101b19–23.
148. 102b4–26, 102b29–35, 155a28–36.
149. Books 4 and 5.

6.2
Non-perspicuously Expressed Definitions

One topic concerned with what is not perspicuously expressed is look to see whether what is said is homonymous with something—for example, if someone[150] says that coming to be is a leading into being, or that health is a balance of hot things and cold things; for leading is homonymous, and so is balance. It is unclear, then, which of the things indicated by what is said in several ways the opponent wishes to state. It is the same way too if the thing defined is said in several ways and he has stated [the definition] without distinguishing them; for then it is unclear of which of them he proposes the definition, and it is also possible to make a trivial objection to it on the grounds that the account does not fit everything he has given the definition of. It is especially possible to make one of this sort when the homonymy is unnoticed. But it is also possible for someone to distinguish himself the various ways in which what is assigned in the definition is stated, and produce a pertinent deduction; for if it is adequately stated in none of the ways, it is clear that he would not have defined it properly.

Another topic is to look to see whether the definer has stated it metaphorically—for example, if he has defined scientific knowledge as "inflexible," or the earth as a "nurse," or temperance as a "harmony";[151] for everything stated metaphorically lacks perspicuousness. Also, it is possible to make a trivial objection to what is stated metaphorically by supposing it to have been stated literally; for then the definition stated will not fit—for example, in the case of temperance; for all harmony consists of notes. Further, if harmony is the kind of temperance, the same thing will be in two kinds, neither of which encompasses the other; for harmony does not encompass virtue, nor virtue harmony.

Further, look to see whether he uses names that are not established, as when Plato[152] defines the eye as "brow-shaded," or the poisonous spider as "bite-necrotic," or marrow as "bone-produced"; for everything that is not customary is non-perspicuous.

But there are some things that are stated neither homonymously nor metaphorically—for example, that the law is a measure or likeness of what is by nature just. Things of this sort are worse than metaphors. For a metaphor in a way makes known the thing it signifies, because of the similarity involved (for all makers of metaphors make their metaphors in accord with a certain similarity), while something of this sort does not make anything known; for there is no similarity in accord with which the law is a measure or likeness, nor is it customarily said to be such in the literal sense. So, if someone says that the law is literally a measure or a likeness, he speaks falsely (for a likeness is something whose coming to be is through an imitation, and

150. Plato, *Sophist* 219b.
151. Plato, *Republic* 430e.
152. The comic Athenian poet.

this is not a feature that belongs to the law). If, on the other hand, it is not literally so, it is clear that he has said something non-perspicuously, and something worse than anything said metaphorically.

Further, look to see whether the account of the contrary is not clear on the basis of what is said; for correctly assigned definitions signify the accounts of the contraries as well. Or, look to see whether, when it is stated by itself, it is not evident what it is the definition of, but rather, like the figures in old-style painters: unless there was an inscription, one used not to recognize who each of them was.

6.3
Definitions Involving Superfluous Material

If, then, the definition is not expressed perspicuously, look at it on the basis of topics such as the preceding ones.

If, on the other hand, the definer has stated the definition in too extended a form, first, look to see whether he has made use of anything that belongs to everything, either to the beings in general, or to those that fall under the same kind as the thing defined; for then it is necessarily stated in too extended a version. For the kind must separate the thing defined from the other things, and the difference must separate it from the ones in the same kind. But what belongs to everything separates it from simply nothing, while what belongs to everything that falls under the same kind does not separate it from those in the same kind, so that this sort of addition is pointless.

Or, again, look to see whether, though the addition is special [to the thing defined], yet, when it is subtracted, the remainder of the account is also special and indicates the substance. For example, in the account of human the addition of "receptive of scientific knowledge" is superfluous; for when it is subtracted the remainder of the account is special and indicates the substance. Simply speaking, anything is superfluous if, when it is subtracted, the remainder makes clear the thing defined. The definition of soul would be of this sort, if indeed it is "number that moves itself";[153] for in fact the soul, as Plato has defined it,[154] is "what moves itself." Alternatively, perhaps what is stated, though special, does not indicate the substance if "number" is subtracted. Which of these holds is difficult to determine perspicuously. But in all such cases one must have an eye to what is advantageous—for example, saying that the definition of phlegm is "the first fluid, produced from nourishment that is unconcocted."[155] For only one thing is first, not many, so that unconcocted is superfluous; for in fact when it is subtracted, the remainder is a special account; for it is not possible for both phlegm and something else to be the first thing to come from the nourishment. Alternatively, perhaps phlegm is not unconditionally the first thing

153. Xenocrates, F85 Isnardi.
154. *Phaedrus* 245e, *Laws* 895e–896a.
155. *GA* 725^{a}15–16.

to be produced from the nourishment, but only the first of the unconcocted ones, so that unconcocted must be added (for stated the other way the account will not be true, if indeed phlegm is not the first of all).

Further, look to see whether something in the account does not belong to all the things that fall under the same form; for an account of this sort defines in a worse way than those that make use of something that belongs to everything; for in the latter way, if the remainder of the account is special, all of it will be special; for it is unconditionally the case that if anything whatever that is true is added to what is special, the whole account becomes special. But if something in the account does not belong to everything that falls under the same form, it is impossible for the whole account to be special; for it will not be counterpredicated of the thing at issue. For example, "two-footed terrestrial animal six feet tall"; for such an account is not counterpredicated of the thing at issue, because six feet tall does not belong to everything that falls under the same form.

Again, look to see whether the definer has said the same thing several times—for example, saying that appetite is a desire for something pleasant; for all appetite is for something pleasant, so that what is the same as appetite will be for something pleasant. [The definition of appetite] becomes, then, "the desire for something pleasant for something pleasant"; for there is no difference between saying appetite and saying the desire for something pleasant, so that either will be for something pleasant.

Alternatively, perhaps this involves no absurdity; for human is also two-footed animal, so that what is the same as human will also be two-footed, but two-footed terrestrial animal is the same as human, so that two-footed terrestrial animal is two-footed. But nothing absurd comes about because of this; for two-footed is not predicated of terrestrial animal (for in this way two-footed would be predicated twice of the same thing); rather, it is about a two-footed terrestrial animal that two-footed is said, so that two-footed is only predicated once. And the case of appetite is similar; for it is not of desire that being for pleasure is predicated but of the whole thing, so that here too the predication occurs only once.

Absurdity results, not when the same name is uttered twice, but when the same thing is predicated of something several times, as happens when Xenocrates says[156] that wisdom is [a science that] defines, and gets a theoretical grasp on, the beings; for a science that defines something is the sort of science that gets a theoretical grasp on it, so that he is saying the same thing twice, when he again adds "and gets a theoretical grasp on." It is the same way too with those who say that coldness is a privation of heat in accord with nature; for every privation is a privation of what belongs in accord with nature, so that it is superfluous to add "in accord with nature," but was enough to say "a privation of heat," since the "privation" itself makes it known that what is meant is the heat in accord with nature.

156. F3 Isnardi.

Again, look to see whether, after a universal has been stated, the definer has added a particular case as well—for example, if one has defined decency as "taking less than one's share of the advantageous and the just";[157] for the just is a sort of advantage.[158] For after stating the universal, he has added a particular case. Also, if he has defined medicine as "scientific knowledge of what is healthy for animal and human," or law as "a likeness of what is by nature noble and just"; for the just is something noble, so that he is saying the same thing several times.

6.4
Whether a Definition Defines an Essence

Whether a definition is given correctly or incorrectly, then, should be looked at by means of these and these sorts of topics. But whether the opponent has defined the essence or not must be looked at on the basis of the following ones.

First, look to see whether he has not produced the definition through prior and better-known things. For since a definition is assigned for the sake of knowing the thing stated, and we know not on the basis of random things, but rather on the basis of prior and better-known ones, just as in the case of demonstrations (for this holds of all teaching and learning), it is evident that the person who has not defined it through such things has not defined it at all. Otherwise, there will be more than one definition of the same thing; for it is clear that a person who has defined it through prior and better known things has also defined it and done so better, so that both would be definitions of the same thing. But they do not seem to be such; for what is precisely the being for each of the beings is one thing. So, if there are several definitions of the same thing, what is precisely the being for the thing defined will be the same as each of the things indicated by the definitions. But these things are not the same, since their definitions are distinct. It is clear, then, that a person who has not **141b1** defined through prior and better-known things has not defined at all.

The fact that the definition has not been stated through better known things may be taken in two ways; for either it is produced from things that are unconditionally less well known or less well known to us; for both ways are possible. Unconditionally, what is prior is better known than what is posterior—for example, a point than a line, a line than a plane, and a plane than a solid, just as a unit is more so than a number; for it is prior to and a starting-point of all number. Similarly, a letter is more so than a syllable. To us, on the other hand, it sometimes happens that the reverse is the case; for the solid falls most under perception, the plane more than the line, the line more than the point. For ordinary people know things of the former sort earlier; for to

157. Plato, ††*Definitions* 412b.
158. *Pol.* 1279a17–19.

learn them is a task for random thought, while to learn the others is a task for exact and extraordinary thought.

Unconditionally, then, it is better to try to make what is posterior known through what is prior; for proceeding in this way is more scientific. Nonetheless, in relation to those who cannot know through things of the latter sort, it is presumably necessary to produce the account through things known to them. Among definitions of this sort are the following ones of the point, the line, and the plane; for all of them indicate prior things through posterior ones; for they say that the point is the limit of the line, the line of the plane, and the plane of the solid. One must not overlook, however, that it is not possible for those who define in this way to indicate the essence of the thing defined, unless it so happens that the same thing is both better known both to us and also unconditionally better known,[159] if indeed a correct definition must define through the kind and the differences, and these are among the things that are unconditionally better known than the form and prior to it. For the kind and the difference do away with the form,[160] so that these are prior to the form. They are also better known; for if the form is known, it is necessary for both the kind and the difference to be also known (for a person who knows human knows both animal and terrestrial), while if the kind or the difference is known, it is not necessary for the form to be known, so that the form is less well known.

Further, those who say that definitions of this sort—those produced from things known to a given person—are in accord with the truth will, as a result, have to say that there are many definitions of the same thing; for different things happen to be better known to different people, not the same things to all, so that a distinct definition would have to be given to each one, if indeed the definition must be produced from things that are better known to each.

Further, to the same people distinct things are better known at distinct times—initially, perceptible things, then, as they become more exact [knowers], the reverse, so that neither must the same definition always be given to the same person by those who say that a definition must be given through the things that are better known to each one.

It is clear, then, that one must not define through these sorts of things, but rather through those that are unconditionally better known; for only in this way would one and the same definition always result. But presumably what is unconditionally known is also what is known not to everyone, but rather to those with good dispositions where their thought is concerned, just as what is unconditionally healthy is what is so to those in a good state where their body is concerned.

Each point of this sort, then, must be made exact, but made use of with an eye to what is advantageous in arguing dialectically. But it is most of all agreed to be possible

159. Cf. *Rh.* 1358ᵃ23–26.

160. I.e., when they are done away with themselves.

to do away with a definition if the definer has produced his account neither from what is unconditionally better known nor from what is better known to us.

One way, then, of not defining by means of things that are better known is to indicate what is prior through what is posterior, as we said previously.[161] Another is if the definer has assigned his account to us of what is at rest and definite through what is indefinite and in movement; for what remains at rest and what is definite is prior to what is indefinite and in movement.[162]

There are three ways of not proceeding from things that are prior. The first is when an opposite has been defined through its opposite—for example, good through bad; for opposites are by nature simultaneous. To some people too it seems that the science of both is the same, so that the one is not better known than the other either. One must not fail to notice, however, that it is presumably impossible to define some things in any other way—for example, the double without the half, and whatever is said to be intrinsically relative to something. For the being for all such things is the same as having some sort of relation to something, so that it is impossible to know the one without the other. That is why it is necessary for the one to be included in the account of the other. We must, then, know all the things of this sort, and make use of them as seems to be advantageous.

Another way is when the definer has made use of the thing defined itself. This goes unnoticed when the name of the thing defined itself is not used—for example, if he[163] has defined the sun as "star that shines by day"; for in using day, he makes use **142^{b}1** of the sun. To uncover these sorts of things, one should substitute the account for the name—for example, that day is the spatial movement of the sun over the earth; for it is clear that a person who has spoken of the spatial movement of the sun over the earth has spoken of the sun, so that in using day, he has made use of the sun.

Again, look to see whether he has defined one co-ordinate member of a division by means of another co-ordinate member—for example, odd number as "one greater by a unit than an even number." For the co-ordinate members of a division drawn from the same kind are by nature simultaneous; and odd and even are co-ordinate members, since both are differences of number.

Similarly, look to see whether he has defined a higher one through a lower one—for example, even number as "what is bipartitely divisible"; or good as "a state of virtue"; for bipartitely is derived from two, which is an even number, and virtue is a sort of good, so that the former are lower than the latter. Further, in making use of what is lower than a thing, one will necessarily make use of the thing itself as well. For a person who makes use of virtue, makes use of good, since virtue is a sort of good, and, similarly, a person who makes use of bipartitely makes use of even, since "bipartitely divisible" signifies divisible by two, and two is an even number.

161. 141^{a}26–^{b}34.
162. *Met.* 1039^{b}31–1040^{a}7.
163. Plato, ††*Definitions* 411b.

6.5
Kind

Speaking in universal terms, then, one topic is not producing the account through things that are prior and better known, and its parts are the ones mentioned.[164] A second is to see whether, though the thing at issue is in a kind, it is not proposed in the kind. This sort of error is found in all cases in which the what-it-is is not proposed first in the account—for example, in the definition of body as "what has three dimensions," or the definition of human, if someone were to define it as "what scientifically knows how to count." For it has not been stated what it is that has three dimensions, or what it is that scientifically knows how to count. The kind, on the other hand, is meant to signify the what-it-is, and, of the things mentioned in the definition, is put first.

Further, look to see whether, though the thing defined is said in relation to several things, the definer has not applied it in relation to all of them—for example, if he has defined grammar as "the scientific knowledge of writing from dictation"; for he should add that it is also that of reading. For a person who assigns "the scientific knowledge of writing" as the definition has no more defined it than one who assigns "the scientific knowledge of reading." So neither of them has defined it, but only the one who has stated both of these things, since there cannot be several definitions of the same thing. In some cases, certainly, what has been said is in accord with the truth, but in some cases it is not—for example, in those in which the definition is not said in relation to both things intrinsically, as when medicine is defined as "what produces health and disease"; for it is said in relation to the first intrinsically, but in relation to the second coincidentally; for, unconditionally, it is foreign to medicine to produce disease. So a person who assigns it in relation to both has no more defined it than a person who assigns it in relation to one of the two. On the contrary, he has presumably done even a worse job, since any practitioner whatever of the remaining ones is capable of producing disease.

Further, look to see whether, though the thing defined is said in relation to several things, the definer has assigned it not in relation to the better but in relation to the worse; for every science and capacity seems to be of what is best.

Again, if what is mentioned is not proposed in its proper kind, look at it on the basis of the elements concerned with the kind, as was stated previously.[165]

Further, look to see whether the definer states the definition in a way that jumps over the kinds—for example, if he defines justice as "the state productive of equality or allocative of what is equal"; for a person who defines in this way jumps over virtue. Leaving out the kind of justice, then, he does not state the essence; for the substance of each thing involves its kind. This is the same as not putting the thing in the closest

164. 141a26–142b19.
165. 139b3–5.

kind; for a person who puts it in the closest one has stated all the higher ones, since all the higher kinds are predicated of the lower ones. So, either it must be put in the closest kind, or else all the differences, through which the closest kind is defined, must be attached to the higher kind; for this way nothing would be omitted, but rather instead of the name, the account of the lower kind would be stated. But a person who states only the higher kind by itself does not state the lower kind as well; for the one who states "plant" does not state "tree."

6.6
Difference

Again, in the case of differences, one must in a similar way look to see whether the definer has mentioned the differences that are those of the kind. For if he has not defined the thing at issue by the differences special to it, or has mentioned a sort of thing that does not at all admit of being a difference of anything (for example, animal or substance), it is clear that he has not defined it; for the things mentioned are not differences of anything whatever. Also, see whether there is anything co-ordinate in a division with the difference mentioned. For if there is not, it is clear that the one mentioned would not be a difference of the kind; for every kind is determined by differences that are co-ordinate members of a division, just as animal is by terrestrial and winged. Or else, see whether, though there is a co-ordinate difference, it is not **143b1** true of the kind. For it is clear that neither of them would be a difference of the kind; for all the co-ordinate differences are true of their proper kind. In a similar way, look to see too whether, though the co-ordinate difference is true of the kind, its being added to it does not make a form. For then it is clear that it would not be a difference of the kind; for every difference, together with the kind, makes a form. If, however, it is not a difference, what is mentioned as a difference would not be a difference either, since it is a co-ordinate of it in a division.

Further, look to see whether he divides the kind by a negation, as those do who define line as "length without breadth"; for this signifies nothing other than that it does not have breadth. The result, then, will be that the kind participates in the form;[166] for every length either is without breadth or has breadth, since of everything either the affirmation or the negation is true, so that the kind of line, which is length, will also either be without breadth or have breadth. But "length without breadth" is the account of a form, as, likewise, is "length having breadth." For without breadth and having breadth are differences, and the account of the form is composed of the difference and the kind, so that the kind would admit of the account of the form. Similarly, it would also admit of the account of the difference, since one or other of the differences just mentioned is of necessity predicated of the kind.

166. Which is impossible. See 121a13–14.

The topic just mentioned is useful against those who posit the existence of Forms. For if there is length-itself, in what way is it to be predicated of the kind having breadth or without breadth? For one or the other of these must be true of every length, if indeed it is going to be true of the kind. But this does not happen; for there are lengths without breadth and lengths having breadth. So this topic is useful only against those who say that every kind is one in number. This, though, is what those who posit the Forms do say; for they say that the kind is length-itself or animal-itself.[167]

But perhaps in some cases it is necessary for the definer to use a negation—for example, in the case of privations; for blind is not having sight when it is natural to have it. But there is no difference between dividing a kind by a negation and by means of the sort of affirmation that must necessarily have a negation as its co-ordinate in a division—for example, if he has defined something as "length having breadth"; for co-ordinate in the division with having breadth is not having breadth, and nothing else, so that again the kind is divided by a negation.

Again, look to see whether he has assigned the form as a difference, as do those who define insolence as "wanton aggression accompanied by satirizing"; for satirizing is a sort of wanton aggression, so that satirizing is not a difference but a form.

Further, look to see whether he has stated the kind as a difference—for example, stating that virtue is a good or excellent state; for good is the kind of virtue. Alternatively, perhaps good is not the kind but the difference, if indeed it is true that the same thing does not admit of being in two kinds, neither of which encompasses the other. For good does not encompass state, nor state good; for not every state is good, nor is every good a state. So they would not both be kinds. If, then, state is the kind of virtue, it is clear that good is not its kind but rather a difference. Further, "state" signifies the what-it-is of virtue, while "good" signifies not what it is but a quality; and a difference seems to signify a quality.[168]

See too whether the assigned difference signifies not a quality but a this something; for it seems that every difference indicates a certain quality.

Look to see too whether the difference belongs coincidentally to the thing defined. For no difference is among the things that belong coincidentally, just as no kind is either; for a difference does not admit of belonging to something and of not belonging to it.

Further, if the difference, the form, or any of the things under the form is predicated of the kind, the thing would not have been defined; for none of the things just mentioned admits of being predicated of the kind, since the kind has the widest extension of all of them. Again, look to see whether the kind is predicated of the difference; for the kind seems to be predicated not of the difference but of the things the difference is predicated of—for example, animal is predicated of human, ox, and other terrestrial animals, not of the difference itself that is said of the form. For if "animal" is going to be predicated of the differences one by one, many animals would

167. Since something is in the kind F by participating in the F-itself.
168. 122b16–17, 128a26–27.

be predicated of the form; for the differences are predicated of the form.[169] Further, all differences will be either forms or individuals, if they are animals; for each animal **144^{b}1** is either a form or an individual.

In a similar way, look to see too whether the form or any of the things under the form is predicated of the difference; for this is impossible, since the difference has a 5 wider extension than the forms.[170] Further, the result will be that the difference is a form, if indeed any of the forms is predicated of it; for if "human" is predicated, it is clear that the difference is [predicatively] human. Again, look to see whether the difference is prior or not prior to the form; for the difference must be posterior to the kind but prior to the form.[171] 10

Look to see whether the stated difference also belongs to a distinct kind, neither encompassed by nor encompassing the first; for the same difference does not seem to belong to two kinds neither of which encompasses the other. Otherwise the result will be that the same form will also be in two kinds neither of which encompasses the other. For each of the differences imports its own proper kind—for example, 15 terrestrial and two-footed import animal along with them. So, if what the difference is predicated of, both of the kinds are also predicated of, it is clear that the form is in two kinds neither of which encompasses the other. Alternatively, perhaps it is not impossible for the same difference to belong to two kinds neither of which encom- 20 passes the other. But "if they do not both fall under the same [kind]" must be added. For "terrestrial" and "winged" are kinds neither of which encompasses the other, and two-footed is a difference of both of them, so that it must be added that they do not both fall under the same [kind]; for they both fall under "animal." It is also clear that 25 it is not necessary for a difference to import every proper kind along with it (since the same difference admits of belonging to two kinds neither of which encompasses the other), but only that it import one or other of the two along with it, as well as all of the higher kinds, just as two-footed imports either winged or terrestrial along with it. 30

See also whether the definer has assigned being in something as a difference of substance; for it seems that one substance does not differ from another by where it is. That is also why people criticize those who divide animals by terrestrial and aquatic,

169. The argument is apparently this: D_1, D_2, and D_3 are the differences of a form S, so that $S = D_1 + D_2 + D_3$. Animal is predicated of D_1, and of D_2, and of D_3 one by one. But because $D1 \neq D2 \neq D3$, the animal that is predicated of them in this way must be a distinct animal in each case, so that the A_1 predicated of $D_1 \neq$ the A_2 predicated of $D_2 \neq$ the A_3 predicated of D_3. (For otherwise D_1, D_2, and D_3 would be one and the same animal, and so would be numerically identical.) Since $S = D_1 + D_2 + D_3$, it follows that $S = A_1 + A_2 + A_3$, so that many distinct animals are predicated of S.

170. The assumption, as in the previous topic, is that the form S is defined by a number of distinct differences, D_1, D_2, and D_3, each of which, taken one by one, has a wider extension than S.

171. The extension of the kind is wider than that of the difference, so that doing away with the kind does away with the difference, but not vice versa, making the kind prior (123^{a}14–15). Similarly, the extension of the difference is wider than the form, making it prior to the form (122^{b}35–123^{a}1).

on the supposition that "terrestrial" and "aquatic" signify the where. Alternatively, perhaps they do not criticize in a correct way; for "aquatic" does not signify "in something" or "where," but a certain quality.[172] For even if the thing is on land, it is nonetheless aquatic. Similarly, a land animal, even if it is in water, will be a land animal, not an aquatic animal. Nonetheless, if the difference ever does signify being in something, it is clear that the definer will have made an error.

Again, look to see whether he has assigned an affection as a difference; for every affection, if it becomes more intensified, utterly alters the substance, but a difference is not like this; for it seems that a difference rather preserves what it is a difference of, and that it is unconditionally impossible for a given thing to be without its own proper difference; for if terrestrial does not exist, human will not exist. And, simply speaking, none of the things with respect to whose possession something undergoes alteration is a difference of it; for all things of this sort, if they become more intensified, utterly change the substance. So, if the definer has assigned anything of this sort as difference, he has made an error. For, unconditionally, we undergo no alteration with respect to our differences.

Also, look to see whether he has not assigned the difference of a relative as relative to something else. For the differences of relatives are themselves relatives—for example, those of scientific knowledge. For it is said to be theoretical, practical,[173] and productive. And each of these signifies a relative. For it is theoretical scientific knowledge of something, productive scientific knowledge of something, and practical scientific knowledge of something.[174]

Look to see too whether the definer assigns each relative as relative to its natural correlative. For in some cases it is possible to use the thing only in relation to the natural one, and in relation to nothing else, while in others it is also possible to use it in relation to something else—for example, the eye can only be used for seeing, but a strigil can also be used as a sort of instrument for drawing off liquid. Nonetheless, if someone had defined a strigil as "an instrument for drawing off liquid," he would have made an error; for that is not its natural correlative. And the definition of a natural correlative is "that for which a practically wise person, and the science proper to the given thing, would use it."

Or again, look to see whether he has not assigned it to the primary correlative, when the thing happens to be said in relation to several—for example, if he has defined practical wisdom as "the virtue of a human or of a soul and not of the rationally calculative part"; for practical wisdom is primarily the virtue of the rationally calculative part; for it is in accord with this that the soul and the human being are said to be practically wise.

Further, if what the thing defined has been stated to be an affection or disposition of is not receptive of it, he has made an error; for every disposition and every affection

172. I.e., a difference. See 144ᵃ18–19.
173. Reading καὶ πρακτικὴ. See 157ᵃ10–11.
174. Reading καὶ πρακτικὴ τινός.

naturally comes to be in what it is a disposition or an affection of—for example, scientific knowledge in the soul, since it is a disposition of soul. But sometimes people make errors in cases of this sort—for example, those who say that sleep is an incapacity of perception, that puzzlement is equality of contrary rational calculations, **$145^{b}1$** or that pain is the splitting apart of naturally grown-together parts, involving force. For sleep does not belong to perception (though it should belong to it, if indeed it is incapacity of perception), and neither, likewise, does puzzlement belong to rational calculations, nor pain to naturally grown-together parts; for inanimate things will feel pain, if indeed pain will be present in them. The definition of health is also of this sort, if indeed it is "a balance of hot and cold things"; for then it is necessary for the hot and cold things to be healthy. For a balance of a given thing belongs in each of the things of which it is the balance, so that health would belong to them. Further, the result for those who define in this way is that what is produced is put in what is productive of it, or the reverse. For the splitting apart of naturally grown-together parts is not pain, but productive of pain, and incapacity of perception is not sleep either, but one is productive of the other; for either we go to sleep because of the incapacity, or we have the incapacity because of sleep. Similarly too, equality of contrary rational calculations would seem to be productive of puzzlement; for when we are rationally calculating both ways [of doing something], and everything that comes about appears to be similar either way, we are puzzled about which of the two to do in action.

Further, look at all the periods of time to see whether there is a discordance somewhere—for example, if immortal has been defined as "animal *aphtharton* now"; for an animal now *aphtharton* will be [only] now immortal [but not at other times]. Alternatively, perhaps this does not follow in this case; for "now *aphtharton*" is ambiguous; for it either signifies that the thing has not passed away now or that it is not capable of passing away now, or that it is now of a sort never to have passed away. When, then, we say that an animal is *aphtharton* now, we mean this: that it is now an animal of a sort never to pass away. But this latter was the same as saying that it is immortal, so that it does not follow that it is now immortal [but not at other times]. Nonetheless, if it happens that what is assigned in accord with the account belongs now or earlier [but not at other times], but what is assigned in accord with the name does not belong [in that way], they would not be the same thing. The topic must, then, be used in the way stated.

6.7
The More and the Less

Look to see too whether the thing defined is said more in accord with something else than in accord with the assigned account—for example, if justice is defined as "capacity allocative of what is equal." For a just person is more one who deliberately chooses to allocate equally than one capable of it, so that justice would not be

146ª1 capacity allocative of what is equal; for then a person who is capable of allocating equally would also be most just.

Further, when the thing at issue admits of the more, look to see whether the one in accord with the assigned account does not admit of it, or—the reverse—whether the one in accord with the assigned account does admit of it, while the thing at issue does not; for either both must admit of it or neither, if indeed what is assigned by the account is the same as the thing at issue. Further, look to see whether, though both admit of the more, they do not both get the increase simultaneously—for example, if love is defined as "appetite for sexual intercourse"; for a person who is more in love does not have more appetite for sexual intercourse, so that they do not both admit of the more simultaneously.[175] But they certainly would have to, if indeed they were the same thing.

Further, two things being proposed, look to see whether what the thing at issue is more said of, the account is less said of—for example, if fire is defined as "the most fine-grained body." For flame is fire more than light is, while flame is the most fine-grained body less than light is. But both should have belonged more to the same thing, if indeed they were the same. Again, look to see whether one belongs in a similar way to both of the things proposed, while the other does not belong in a similar way to both, but more to one of them.

Further, look to see whether he assigns the definition in relation to two things, taken severally—for example, if he defines beautiful as "pleasant to sight or pleasant to hearing,"[176] or being as "capable of being affected or capable of affecting"; for then the same thing will be both beautiful and not beautiful, and likewise, will both be and not be. For pleasant to hearing will be the same as beautiful, so that not pleasant to hearing will be the same as not beautiful; for the opposites of things that are the same are themselves the same, and not beautiful is the opposite of beautiful, and not pleasant to hearing the opposite of pleasant to hearing. It is clear, then, that not pleasant to hearing is the same as not beautiful. If, then, something is pleasant to sight but not to hearing, it will be both beautiful and not beautiful. And in a similar way we will prove that the same thing both is and is not.

Further, of kinds, differences, and all the other things assigned in definitions, put accounts in place of names and look to see whether there is any discordance.

6.8
Definitions of Relatives

If the thing defined is a relative, either intrinsically or with respect to its kind, look to see whether the definer has not stated in the definition what it is said relative

175. The idea might be better conveyed the other way around: when the appetite is sated by actual intercourse, love is not simultaneously lessened.
176. Plato, *Hippias Major* 298a.

to, either intrinsically or with respect to its kind—for example, if he has defined scientific knowledge as "supposition incapable of being persuaded to change," or **146ᵇ1**
wish as "desire without pain"; for the substance of everything relative is relative to something else, since the being for each relative is the same thing as it precisely having some relation to something. He should, then, have said that scientific knowledge is supposition about the scientifically knowable, and that wish is desire for the good. It 5
is the same way too if he has defined grammar as "scientific knowledge of letters"; for he should have assigned in the definition either what grammar itself is relative to or what the kind is relative to. Or, again, look to see whether, although the relative has been stated, it is not assigned in relation to its end; and the end in a given case is the best thing or what the other things are for the sake of. The best one, then, must be 10
stated, or the ultimate one—for example, appetite must be defined not as "for what is pleasant," but "for pleasure"; for it is for the sake of pleasure that we also choose what is pleasant.

Look to see too whether what he has assigned the definition in relation to is a coming to be or an activity; for nothing of these sorts is an end; for having finished the activity or having finished the coming to be is more an end than the coming to be and the being active. Alternatively, perhaps this is not true in all cases; for pretty 15
much everyone wishes to be pleased more than to have ceased to be pleased, so that the activity is more of an end than having finished it.

Again, in certain cases, one must look to see whether he has not determined the quality, quantity, place, or other relevant differences of the thing—for example, with 20
an honor-lover, the quality or quantity of honor he desires; for everyone desires honor. So it is not enough to say that an honor-lover is a person who desires honor, but one must add the differences just mentioned. Similarly, with a money-lover too, the quantity of money he desires, or with a person who lacks self-control, the quality 25
of pleasure he is concerned with; for it is not a person controlled by any pleasure whatever who is said to lack self-control, but the one controlled by certain pleasures.[177] Or, again, when people define night as "a shadow over the earth," earthquake as "a movement of the earth," cloud as "a condensation of air," or wind as "movement of air"; for quality, quantity, and due to what must be added. And similarly in other 30
cases of this sort; for when one leaves out any difference whatever, one does not state the essence. And one must always attack what is deficient; for not just any manner of movement of the earth whatever or any quantity of it whatever is an earthquake, nor similarly is any manner of movement whatever of any quantity of air whatever wind. 35

Further, in the case of desires, and in the case of any other things where it is fitting, look to see whether the definer has not added "apparent"—for example, in saying that wish is a desire for good, or appetite a desire for pleasant, instead of for apparent good or apparent pleasant. For often the thing that is good or pleasant escapes the **147ᵃ1**
notice of those who feel desire, so that [what they desire] is not necessarily good or

177. *NE* 1118ᵇ6–8.

pleasant but only apparently so. He should, then, have made the one he assigns in this way. On the other hand, if a person who posits the Forms does assign the addition just mentioned, he must be led to the Forms. For there is no Form of anything that is [merely] apparent, but a Form seems to be said in relation to a Form—for example, appetite-itself for pleasant-itself[178] and wish-itself for good-itself. They will not, then, be for the apparent good nor for the apparent pleasant. For it is absurd for there to be an apparent good-itself or pleasant-itself.

6.9
State and Privation, Relatives, and Opposites

Further, if the definition is of the state [or having], look at what has it, or if of what has it, look at the state, and similarly in all cases of this sort—for example, if the pleasant is precisely the beneficial, the one who is pleased is benefited. Speaking in universal terms, in definitions of this sort, the definer in a way defines more than one thing. For a person who defines scientific knowledge in a way also defines ignorance, and likewise he also defines what has scientific knowledge and what lacks scientific knowledge, and knowing scientifically and being ignorant; for when the first has become clear, in a way the remaining ones also become clear. Look, then, in all cases of this sort, to see whether there is not some discordance, making use of the elements [or topics] based on contraries and co-ordinates.[179]

Further, in the case of relatives, look to see whether the form is assigned relative to what the kind is assigned relative to. For example, if supposition is relative to supposable, see whether this sort of supposition is relative to this sort of supposable, and if the multiple is relative to the fraction, whether this sort of multiple is relative to this sort of fraction; for if it has not been given in this way, it is clear that an error has been made.

See too whether the account of the opposite is the opposite account—for example, whether the opposite of the account of the double is the account of the half; for if the double is what exceeds the equal, half is what is exceeded by the equal. And in like manner in the case of contraries; for the contrary account will be that of a contrary, in accord with one or other of the combinations of the contraries. For example, if beneficial is what is productive of good, harmful is what is productive of bad or destructive of good; for one or other of these is necessarily contrary to what was stated
147b1 initially. If, then, neither of them is the contrary of what was stated initially, it is clear that neither of the accounts assigned later would be the account of the contrary, so that the one assigned initially would not be correctly assigned either.

178. Plato, *Republic* 437e.
179. 2.9.

Since some contraries are said of things as one being a privation of the other (for example, inequality seems to be a privation of equality, for unequal is said of things that are not equal), it is clear that a contrary that is said of things as a privation is necessarily defined through the other one, while the one remaining [to be defined] cannot then be defined through the one said in accord with a privation; for then the result would be that each would be known through the other. Be on the lookout, then, in the case of contraries, for an error of this sort—for example, if someone were to define equality as "the contrary of inequality"; for he is defining through what is said of things in accord with a privation. Further, a person who defines in this way necessarily makes use of the thing itself that is being defined. And this becomes clear if the account is substituted for the name; for saying inequality is no different from saying the privation of equality. Equality, then, will be the contrary of the privation of equality, so that the thing itself would be being used.

If neither of the contraries is said of things in accord with a privation, but the account is assigned in a similar way, for example, good is the contrary of bad, it is clear that bad will then be the contrary of good; for the account of things contrary in this way must be assigned in such a way. And so the result again is that the definer makes use of the thing itself that is being defined; for the good belongs in the account of the bad. And so if good is the contrary of the bad, and bad is no different than the contrary of the good, good will be the contrary of the contrary of good. It is clear, then, that it itself has been used.

Further, look to see whether in assigning what is said in accord with a privation, the definer has not assigned what it is a privation of—for example, of the having of something, of the contrary, or of whatever it is the privation of. Also, whether he has not added what it naturally comes to be in, either unconditionally or what it naturally comes to be in primarily. For example, if having said that ignorance is a privation, he has not said that it is a privation of scientific knowledge, or has not added what it naturally comes to be in, or, though he has added this, has not assigned what it naturally comes to be in primarily—for example, saying not that it is in the rationally calculative part but in human or soul; for if there is any of these things whatever that he has not done, he has made an error. It is the same way too if he has not said that blindness is a privation of sight in the eye; for in correctly assigning the what-it-is one must also assign what it is a privation of and what it is that is deprived. **148ᵃ1**

See too whether he has not defined by a privation what is not said in accord with a privation—for example, in the case of ignorance, this sort of error would seem to be committed by those who say what ignorance is in accord with negation.[180] For what has no scientific knowledge seems not to be ignorant, but more so what is utterly deceived. That is why we do not say that inanimate things or children are ignorant. So ignorance is not said of things in accord with the privation of scientific knowledge.

180. *APo*. 79ᵇ23–24.

6.10
Inflections, Forms, Homonyms, Synonyms, Things Said in Many Ways

Further, look to see whether the inflections of the account fit with the corresponding inflections of the name—for example, if beneficial is what is productive of health, whether beneficially is productively of health, and what has brought a benefit is what has produced health.

Look to see too whether the definition stated fits the Form as well. For in some cases this does not happen—for example, as Plato defines[181] animals, adding "mortal" in their definitions; for the Form (for example, human-itself) is not mortal, so that the account will not fit the Form. Unconditionally, in those cases where capable of affecting something or capable of being affected by something is added, it is necessary for there to be discord when the definition is applied to the Form; for Forms seem to be unaffectable and immovable to those who say there are Forms.[182] Against these people even arguments of this sort are useful.

Further, look to see whether he has assigned one common account to things said [to be what they are] homonymously; for things are synonymous when the account corresponding to their name is one. So the assigned definition will fit none of the things falling under the name, if indeed it fits all of the homonymous things equally. This is what happens in fact to Dionysius'[183] definition of life, if indeed it is "a congenital movement inseparably connected to a kind of beings capable of nourishment"; for this belongs no more to animals than to plants. Life, however, seems not to be said of things in accord with one form, but one form seems to belong to animals and a distinct one to plants.

It is also possible to deliberately choose to assign the definition as a synonym and to speak of all life in accord with one form. But there is also nothing to prevent someone, even if he sees the homonymity and wishes to assign the definition of one of the two homonyms, from unwittingly assigning an account that is not special to it but common to both. Nonetheless, if he has done either of these things, he has committed an error. Since homonyms sometimes go unnoticed, when questioning, treat them as synonyms (for the definition of the one will not fit the other, so that it will not seem to be [correctly] defined this way, since it must fit everything that is synonymous), but, when answering oneself, distinguish them. Since some answerers say, on the one hand, that what is synonymous is homonymous, when the assigned account does not fit all cases, and, on the other hand, that what is homonymous is synonymous, when it fits both cases, one must obtain an agreement beforehand

181. No such definition occurs in Plato's extant writings.
182. Reading τοῖς λέγουσιν ἰδέας εἶναι. See 154a18–20.
183. Probably the little-known Dionysius the Sophist, mentioned at ††*Physiognomics* 808a16.

on these matters or else pre-deduce[184] that the thing is a homonym or a synonym, whichever of the two [is most useful]; for people concede something more readily when they do not foresee what the result will be.

If, however, when there has been no agreement, someone says that what is synonymous is homonymous because the account he has assigned does not also fit this case, look to see whether the account of the case in question fits the remaining cases as well, since then it is clear that it would be synonymous with the remaining ones. Otherwise, there will be several accounts of the remaining cases. For the two accounts that are in accord with the name fit them: both the one assigned earlier and the one assigned later.

Again, if someone, defining something said of things in many ways, and finding that the account does not fit all the cases, were to say not that the thing is homonymous, but that the name does not apply to all of them, because the account does not apply to them either, one must say to such a person that one must use the traditional and constantly attributed names, though in some cases[185] one should not speak in the same way as ordinary people.

6.11
Complexes, Composites, and Substitution of Names

If a definition has been proposed of something complex, subtract the account of one of the components of the complex, and look to see whether the remainder is an account of the remainder; for if it is not, it is clear that neither is the whole an account of the whole. For example, if someone[186] has defined limited straight line as "limit of a plane having limits whose mid-point blocks the view of the limit-points," and if the account of limited line is "limit of a plane having limits," that of straight must be the remainder: whose mid-point blocks the view of the limits. But an unlimited line, though straight, has neither a mid-point nor limit-points, so that the remainder is not the account of the remainder.

Further, when what is being defined is a composite, look to see whether the assigned account is isomerous to what is being defined. An account is said to be isomerous when the component parts in the thing are as many as the nouns and verbs in its account. For it is necessary, in cases of this sort, for the substitution to be name for name, either in the case of some or of all, since no more names are uttered now than before, while a person giving a definition must assign an account in place of the **149^{a}1** names, preferably in place of all, but if not, then of most. For in the former way, in the case of simple things too, a person who had changed the name would have given a definition—for example, substituting "cloak" for "cape."

184. 156^{a}7–8.
185. 110^{a}14–22.
186. Plato, *Parmenides* 137e.

Further, and a greater error, look to see whether he has made a substitution for names that are even less well known—for example, "glistening mortal" for "pale human"; for not only has it not been defined, but it is less perspicuous stated this way.

Look to see too whether in the exchange of names it does not any more signify the same thing—for example, if theoretical scientific knowledge has been said to be theoretical supposition. For supposition and scientific knowledge are not the same; but they should be, if indeed the whole thing is going to be the same. For "theoretical" is common to both accounts, but the remainder is different.

Further, look to see whether in making a substitution of one or other of the names he has made a substitution not of the difference but of the kind, as in the example just stated. For theoretical is less well known than scientific knowledge; for the latter is a kind, the former a difference, and the kind is best known of all. So the substitution should have been made not of the kind but of the difference, since the latter is less well known. (Alternatively, perhaps this objection is ridiculous; for there is nothing to prevent the difference from being stated by the better-known name, not the kind. In which case, it is clear that it is for the name of the kind, not of the difference, that the substitution must be made.[187]) But if he is substituting not a name for a name but an account for a name, it is clear that it is of the difference rather than of the kind that an account should be assigned, since the definition is given for the sake of making the thing known; for the difference is less well known than the kind.

6.12
Errors in Definitions

If the definer has assigned the definition of the difference, look to see whether the assigned definition is common to something else as well. For example, if he has said that odd number is "number that has a middle." For number belongs in common to both accounts, but it is for odd that he has made the substitution. But a line and a body also have a middle, though they are not odd. So this would not be a definition of odd. On the other hand, if things are said to have a middle in many ways, in what way something has a middle must be defined. So that there will be a criticism to make, or a deduction that he has not given a definition.

Again, look to see whether he has assigned a definition of something that is of one of the beings, while what falls under the account is not one of the beings—for example, if he has defined white as "color mixed with fire"; for it is impossible for
149b1 what is bodiless to be mixed with body, so that there could not be color mixed with fire, but there is white.

187. Reading ἢ τοῦτο . . . ποιητέον.

Further, those who, in the case of relatives, do not determine what the thing is said in relation to, but, in stating it, include it among too many things, are either wholly or partly mistaken—for example, if someone said that medicine is the science of being. For if medicine is the science of none of the beings, it is clear he was wholly mistaken, while if it is the science of some, but not of others, partly mistaken; for it must be the science of all beings, if indeed it is said to be such intrinsically, and not coincidentally, as holds of all the other relatives; for everything scientifically knowable is said to be such relative to science. It is the same way too with the others, since all relatives are convertible.[188] Further, if indeed a person assigning not intrinsically, but coincidentally, is correctly producing what he assigns, each relative would be said not in relation to one thing, but in relation to several. For there is nothing to prevent the same thing from being a being, a white thing, and a good thing, so that one would be assigning correctly if one assigned in relation to any of these whatever, if indeed a person assigning coincidentally is assigning correctly. Further, it is impossible for an account of this sort to be special to what it is assigned as the account of; for not only medicine, but the majority of the other sciences as well, are said in relation to being, so that each of these will be a science of being.[189] It is clear, then, that a definition of this sort is not the definition of any science whatever; for the definition must be special and not common.

Sometimes people define not the thing at issue but the thing at issue in its good state or when complete. Of this sort are the definition of the orator and of the thief, if indeed an orator is defined as "a person who gets a theoretical grasp on what is persuasive on a given occasion and leaves nothing out," while a thief is defined as "a person who takes things by stealth"; for it is clear that if each is of that sort, one will be a good orator and the other a good thief. For it is not the one who takes by stealth, but rather the one who wishes to take by stealth, that is the thief.

Again, look to see whether he has assigned what is choiceworthy because of itself either as productive or practical or in some other way choiceworthy because of something else—for example, saying that justice is what is preservative of laws, or that wisdom is what is productive of happiness; for what is productive or preservative is one of the things choiceworthy because of something else. Alternatively, perhaps there is nothing to prevent what is choiceworthy because of itself from also being choiceworthy because of something else, but nonetheless a person who has defined what is choiceworthy because of itself in this way has made an error; for what is best in a given thing is most of all in its substance, and what is choiceworthy because of itself [in that thing] is better than what is choiceworthy [only] because of something else, so that it is the former that the definition should have signified more.

188. 125ᵃ5–13.
189. *APo*. 100ᵃ6–9.

6.13
Compound Definitions

Look to see whether the definer in assigning a definition of something has defined it
150a1 as "these things here," or "what is composed of these," or as "this one plus that one."

For if he defines it as "these things here," the result will be that it belongs to both and neither—for example, if he has defined justice as "temperance and courage"; for if there are people each of whom has one of these, both will be just and neither will, since the two together will have justice, while each individually will not. If what has been said is not yet utterly absurd, because this sort of thing does happen in other cases (for there is nothing to prevent two people together from having a mina, though neither individually has it), well, at any rate, that contraries should belong to these people would seem to be completely absurd. This is what will happen if one of them has temperance and cowardice, the other courage and intemperance; for both together will have justice and injustice; for if justice is temperance and courage, injustice will be cowardice and intemperance. In general too the ways of arguing dialectically that the parts and the whole are not the same are all useful against what we are now discussing; for it seems that a person who defines in this way is saying that the parts are the same as the whole. These arguments are most of all proper to cases where the mode of composition of the parts is immediately clear, as in the case of a house or other things of that sort; for then it is clear that, though the parts exist, there is nothing to prevent the whole from not existing, so that the parts are not the same as the whole.

If, however, he has said not that what is being defined is "these things," but rather "what is composed of them," first look to see whether it is not natural for one thing to come to be from the things mentioned; for some things stand in such relation to each other that no one thing can come to be composed of them—for example, a line and a number. Further, look to see whether what is being defined naturally comes to be in one thing primarily, while the things he has said it is composed of do not come to be in one thing primarily, but each in a distinct thing. For then it is clear that it would not be composed of them; for the things the parts are in, the whole too necessarily belongs in, so that the whole is not in one thing primarily, but in several. If, though, both the parts and the whole are each in some one thing primarily, look to see whether they are not in the same one, but rather the whole in one thing and the parts in another.

Again, look to see whether the parts pass away together with the whole; for the reverse must happen: if the parts pass away, the whole does, but if the whole passes away, it is not necessary for the parts to pass away too.

Or, again, look to see whether the whole is good or bad, but the parts neither, or the reverse, the parts good or bad, but the whole neither; for it is impossible for something either good or bad to be composed of things that are neither, or for one
150b1 composed of bad or good things to be neither. Or, again, look to see whether one

thing has more good in it than the other has bad, yet what is composed of them is not more good than bad—for example, if shamelessness is composed of courage and false belief; for courage is more good than false belief is bad. What is composed of them, then, should have followed along with this more, and be either unconditionally good or more good than bad. Alternatively, perhaps this is not necessarily so, if each of the two things is not intrinsically good or bad; for many of the things that are productive [of something] are not intrinsically good, but only when mixed together, or the reverse, are each individually good, but when mixed together are bad or neither good nor bad. What we are now speaking of is most visible in the case of things conducive to health or to disease; for some drugs are such that each individually is good, but if both are administered mixed together, bad.

Again, look to see whether the whole, when composed of a better and a worse [part], is not worse than the better and better than the worse. Alternatively, perhaps this is not necessarily so either, unless things from which it is composed are not intrinsically good, otherwise there is nothing to prevent the whole from not being good, as in the examples just mentioned.

Further, look to see whether the whole is synonymous with one of its parts; for it must not be, any more than in the case of syllables; for the syllable is not synonymous with any of the letters of which it is composed.

Further, look to see whether the definer has not stated the mode of composition; for to state what the thing is composed of is not by itself sufficient to make it known. For the substance of a given composite is not what it is composed of but in what way it is composed of what it is composed of, as in the case of a house; for these things composed in any way whatever are not a house.

But if he assigns this one plus that one as his definition, the first thing one must say is that this plus that is the same either as these things here or as what is composed of them; for a person who speaks of honey plus water is speaking either of honey and of water or of what is composed of honey and water. So, if he agrees that this plus that is the same as either of the things mentioned, it will be fitting to say the very same things as were said before against each of them.

Further, distinguish in how many ways things are said to be one thing plus another, and look to see whether the thing in question is in no way a this plus that. For example, if "this plus that" is said as [two things] being in the same thing receptive of them (as justice and courage are in soul), or else, as being in the same place or in the same period of time, and if this is in no way true of the things in question, it is clear that the assigned definition would not be a definition of anything, since the thing in question is no way a "this plus that." If, however, of the ways distinguished, it is true that each of the two things belongs in the same period of time, look to see whether **151^{a}1** it is possible that it is not in relation to the same thing that each of them is said to be such. For example, if courage has been defined as "daring plus correct thinking"; for it is possible to have daring to steal and correct thinking about matters of health, but a person who has this plus that in the same period of time is in no way courageous.

Further, look to see too whether both of them are said of things in relation to the same thing (for example, in relation to what is healthy); for there is nothing to prevent someone from having both daring and correct thinking in relation to medical matters. Nonetheless, a person who has "this plus that" in this way is not courageous either. For each of the two must be said of things neither in relation to distinct things nor in relation to the same random thing, but in relation to the end that is the end of courage—for example, in relation to the dangers of war, or of something else, if there is something else that is more its end than this.

Some definitions that are assigned in this way do not at all fall under the division of ways just mentioned—for example, that of anger as pain plus a supposition of being treated with contempt. For that the pain comes about because of a supposition of this sort is what the definition wishes to indicate. But the "coming about because of this" is not the same as "this plus that" in any of the ways just mentioned.

6.14
Recapitulation and Conclusion

Again, if the definer has stated that the whole is a composite of these things here (for example, that animal is a composite of soul and body), first look to see whether he has not stated what sort of composite, as, for example, if flesh or bone is defined as "a composite of fire, earth, and air." For it is not enough to speak of composition, but rather one must in addition determine what sort of composition; for it is not that once these things are composed in any way whatever the flesh comes to be, but composed in this way, flesh does, composed in that way, bone. It seems that neither of the things just mentioned is at all the same as a composite; for, for every composite, there is a contrary dissolution, while of the things that were mentioned nothing is a contrary. Further, if it is equally persuasive that everything that is composed is a composite, or else that none is, and, of the animals, each is composed but is not a composite, neither would any of the other things that are composed be a composite.

Again, if it is equally well natural for a pair of contraries to belong to a certain thing, and if he has defined it through one of the two, it is clear that he has not defined it. Otherwise, the result will be that there are several definitions of the same thing; for in what way is the person who has stated it through this contrary giving more of a definition than the one who has stated it through the other, since both equally well occur naturally in it? The definition of soul, if we define it as "substance receptive of scientific knowledge," is of this sort; for it is also equally well receptive of ignorance.

Also, even if one cannot attack the definition as a whole, because the whole is not known, one must attack some part of it, if it is known and it is evident that it has not been correctly assigned; for if a part is done away with, the whole is also done away with. When, again, definitions are non-perspicuous, having corrected and at

the same time reconfigured them so as to have something to attack, in this way proceed to examine them; for it is necessary for the answerer either to accept the assumption of the questioner or make perspicuous himself what exactly is indicated by the account. Further, just as in assemblies it is customary to introduce a law, and if what is introduced is better, to abrogate its predecessor, one should do the same in the case of definitions, and adduce another definition oneself; for if it is evident that it is better and more indicates what is being defined, it is clear that the definition that was proposed will have been done away with, since there are never several definitions of the same thing.

Against all definitions, not the least important element [or topic] is to take a good guess oneself at defining the thing proposed, or else adopt some correctly stated definition; for it is necessary, by looking at a paradigm, as it were, to see clearly what is missing from the things that the definition must have and what is superfluously proposed in addition, so as to be better equipped with lines of attack.

About definitions, then, let this much be said.

BOOK 7

7.1
Sameness and Distinctness

Whether things are the same or distinct, in the strictest of the ways that are mentioned concerning the same—and it was said[190] that what is numerically one is what is in the strictest sense the same—must be looked at on the basis of their inflections, co-ordinates, and opposites. For if justice is the same as courage, the just person is the same as the courageous one, and justly the same as courageously. And similarly in the case of their opposites; for if these things are the same, their opposites—in accord with whatever ways things are said to be opposites—are as well; for it makes no difference whether one takes this or that opposite, since they are the same. Again, look on the basis of the things that are productive or destructive of the things in question, the comings to be and passings away of them, and, in general, at the things that stand in a similar relation to each of them; for when things are unconditionally the same, their comings to be and passings away are the same, as are the things productive and destructive of them.

Look to see too, when one of the two things is said to be most of all something or other, whether the other of the same two things is said to be most of all something or other in the same respect. For example, Xenocrates[191] demonstrates that the happy life and the excellent one are the same, since of all lives the excellent one and the happy

190. $103^{a}23$–24.
191. Fr. 158 Isnardi.

one are most choiceworthy; for only one thing is most choiceworthy and greatest. It is the same way too in other cases of this sort. But each of the two things said to be greatest or most choiceworthy must be numerically one thing. Otherwise, it will not have been proved that they are the same. For it is not necessary, if the Peloponnesians and the Spartans are the most courageous of the Greeks, that the Peloponnesians are the same as the Spartans, since Peloponnesian is not numerically one thing, nor is Spartan, but rather what is necessary is that the one be encompassed by the other, as the Spartans are by the Peloponnesians. Otherwise, the result will be that each is better than the other, if one is not encompassed by the other. For it is necessary for the Peloponnesians to be better than the Spartans, if indeed one is not encompassed by the other; for they are better than all the rest. But similarly it is necessary for the Spartans also to be better than the Peloponnesians; for they too are better than all the rest. So each is made to be better than the other. It is clear, then, that what is said to be best and greatest must be numerically one thing if it is going to be proved to be the same [as another thing]. That also is why Xenocrates has not demonstrated it; for neither the happy life nor the excellent life is numerically one thing, so that it is not necessary for them to be the same due to the fact that both are most choiceworthy, but only for one to fall under the other.

Again, look to see whether, when one of two things is the same as [a third] something, the other is too; for if they are not the same as the same [third] thing, it is clear that neither are they the same as each other.

Further, look at them on the basis of their coincidents or on the basis of the things of which they are coincidents; for whatever is a coincident of one must be a coincident of the other, and whatever one is a coincident of, the other must also be a coincident of. But if there is any discordance among any of these, it is clear that the things are not the same.

See too whether they are not both in one kind of predication, but rather one indicates a quality, the other a quantity or a relation. Again, see whether the kind of each is not the same, but rather one is good, the other bad, or the one virtue and the other scientific knowledge. Or whether, though the kind is the same, the differences predicated of either of them are not the same ones, but rather that of one is theoretical scientific knowledge, that of the other practical. It is the same in the other cases too.

Further, on the basis of the more, look to see whether one admits of the more, while the other does not; or whether both admit of it, but not at the same time, just as the one who loves more does not have more appetite for sexual intercourse, so that love and appetite for sexual intercourse are not the same thing.

Further, on the basis of addition, look to see whether each added to the same thing does not make the same wholes; or whether subtracting the same thing from each leaves a distinct remainder—for example, if someone has said that double of half and multiple of half are the same thing. For then, if "of half" is subtracted from each, the remainders should indicate the same thing, but they do not. For double and multiple do not indicate the same thing.

And look to see not only whether something impossible follows right away because of the thesis, but also whether it is possible for something impossible to come about from a hypothesis to bring one about, as, for example, happens to those who say that void and full of air are the same thing;[192] for it is clear that, if the air went out, it will not be less of a void but more of one, though it will no longer be full of air. So, on a certain hypothesis, whether false or true (it makes no difference which), one thing is done away with, while the other is not. So they are not the same.

To speak in universal terms, look on the basis of every predicate whatever of each of the two things, and of everything of which they are predicated, to see whether there is any discordance anywhere; for whatever is predicated of the one must be predicated of the other, and whatever the one is predicated of, the other must also be predicated of.

Further, since things are said to be the same in many ways, look to see whether the things in question are also the same in another way; for things that are the same [only] in form or in kind cannot possibly be numerically the same. But what we are looking at is whether it is in the latter way that they are the same or not the same.

Further, look to see whether it is possible for one to be without the other; for then they would not be the same thing.

7.2
Sameness and Definition (1)

The topics related to sameness, then, are this many. And it is clear from what has been said that all the topics capable of disestablishing sameness are also useful against a definition, as was said previously;[193] for if the name and the account do not indicate the same thing, it is clear that the assigned account would not be a definition. On the other hand, none of the topics capable of establishing sameness are useful in **153^{a}1** relation to a definition; for it is not enough to have proved that what falls under the account is the same as what falls under the name in order to have established that it is a definition, but rather the definition must have all the other features we prescribed.[194]

7.3
Sameness and Definition (2)

Always try, then, to do away with a definition in this way and through these things. But if we wish to establish one, the first thing to know is that none or few of those who argue dialectically deduce a definition, but all take something of this sort as a

192. *Ph.* 213^{a}22–^{b}2.
193. 102^{a}11–14.
194. 139^{a}25–35.

starting-point—for example, those people who are concerned with geometry and arithmetic as well as the other such branches of learning. The next thing to know is that it belongs to another study[195] to give an exact account of what a definition is and how one must define things. Now, though, to do so with an eye to present needs is enough, so that it is necessary to say only this much: that it is possible for there to be a deduction of a definition and of the essence of the thing at issue. For if a definition is an account indicating the essence of the thing at issue, and if the predicates in the definition must be the only ones predicated in the what-it-is of the thing at issue, and if the kinds and the differences are predicated in the what-it-is, it is evident that if one assumed that only these are predicated in the what-it-is of the thing at issue, then the account containing these would of necessity be a definition; for it is not possible for anything else to be a definition, since nothing else is predicated in the what-it-is of the thing at issue.

That there is room, then, for a deduction of a definition is evident. On the basis of what things a definition must be established has been determined more exactly elsewhere,[196] but for the proposed methodical inquiry the same topics are useful. For it is necessary to look into the contraries and the other opposites, and to do so looking at the whole accounts and at their parts; for if the opposite account is a definition of the opposite, the stated one is necessarily the definition of the thing proposed. Since opposites combine in several ways, take from among the contraries the one, whichever it is, whose contrary definition is most evident.

Look at the whole accounts, then, in the way just stated, but at their parts as follows. First, see that the assigned kind is correctly assigned. For if the contrary thing is in the contrary kind, and the thing proposed is not in the same kind, it is clear that it would be in the contrary one, since it is necessary for contraries to be in the same kind or in contrary kinds. Also, we think that the differences that are predicated of contrary things are contraries, like those of white and black; for the one is contracting and the other dilating of sight.[197] So, if contrary differences are predicated of the contrary thing, then the assigned ones would be predicated of the thing proposed, so that, since both the kind and the differences have been correctly assigned, it is clear that the one assigned would be the definition. Alternatively, perhaps it is not necessary for contrary differences to be predicated of contrary things unless the contrary things are in the same kind, while for those whose kinds are contraries, there is nothing to prevent the same difference from being said of both—for example, of justice and of injustice; for the one is a virtue and the other a vice of soul, so that "of soul" is said as a difference in both cases, since there is also vice and virtue of body. But this is true, at any rate, that the differences of contraries are either contrary or the same. If, then, the contrary difference is predicated of the contrary thing, but not of the one in question, it is clear that the stated difference would be predicated of it. To speak in universal terms,

195. *APo*. 2.3–13.
196. *APo*. 2.13.
197. 107b29–31.

since a definition is composed of kind and differences, if the definition of the contrary is evident, the definition of the thing proposed will also be evident. For since the contrary is either in the same kind or in the contrary one, and likewise the differences predicated of contraries are either contrary or the same, it is clear that either the same kind would be predicated of the thing proposed precisely as of its contrary too, while its differences are either all contrary or else some are contrary and the remaining ones the same; or, the reverse, the differences are the same and the kinds contrary; or both the kinds and the differences are contrary. For it is not possible for them both to be the same; otherwise, the contraries would have the same definition.

Further, look on the basis of inflections and co-ordinates; for here it is necessary for kinds to follow along with kinds, and definitions with definitions. For example, if forgetfulness is the loss of scientific knowledge, to forget will be to lose scientific knowledge, and to have forgotten will be to have lost scientific knowledge. If, then, any one of these whatever is agreed to, it is necessary for the remaining ones to be agreed to as well. Similarly too, if destruction is dissolution of substance, to be destroyed is to have one's substance dissolved, and destructively is dissolvingly. And if destructive is dissolvative of substance, again destruction is dissolution of substance. And similarly in the case of the others. So, if any of them is accepted, all of the remaining ones are agreed to as well.

Also, look on the basis of things that have similar relations to each other. For if what conduces to health is productive of health, what conduces to a good state will be productive of a good state, and beneficial will be productive of good. For each of the things mentioned has a similar relation to its proper end, so that if the definition of one of them is "productive of the end," this would also be the definition of each of the remaining ones.

Further, look on the basis of the more and the equally in all the ways in which it is possible to establish something by comparing things two by two. For example, if this is more a definition of that than this other is of that other, and the one that is less so is a definition, the one that is more so is as well. Also, if this is equally a definition of that as this other is of that other, and if one or other of the two is a definition of the other, so is the remaining one of the remaining one. But when one definition is compared to two things, or two definitions with one thing, looking at them on the basis of the more is not at all useful; for there cannot be one definition of two things, or two definitions of the same thing.

7.4
The Handiest Topics

Also, the handiest of the topics are those just mentioned and those based on co-ordinates and inflections. That is why indeed one must master these most of all and have them ready to hand; for they are most useful in relation to the most cases. And

of the others, the most common ones are the handiest (for these are the most effective of the remaining ones)—for example, looking at the particular cases and looking at the various forms to see whether the account fits them, since the form is synonymous. This sort of procedure is useful against those who posit Forms, as was stated previously.[198] Further, look to see whether the opponent has used a name metaphorically, or predicated it of itself as if it were something else. Also, look to see whether there is any other of the topics that is common and effective.

7.5
Establishing versus Disestablishing a Definition

That it is more difficult to establish than to disestablish a definition is evident on the basis of the things that will be said next. For in fact to see for oneself and to get from those being questioned the relevant sort of premises is not easy—for example, that of the things in the assigned account, one is kind, the other difference, and that the kind and difference are predicated in the what-it-is. Without these it is impossible for a deduction of a definition to come about. For if some other things are also predicated in the what-it-is of the thing at issue, it is unclear whether the one stated or another one is the definition of it, since a definition is an account signifying the essence.

This is also clear from the following considerations. It is indeed easier to draw one conclusion than many. When doing away with a definition, then, it is enough to argue dialectically against one point; for if we have disestablished any one point whatever, we will have disestablished the definition. When establishing one, on the other hand, it is necessary to infer that all the things in the definition belong in it.

Further, when establishing, one must adduce a universal deduction; for it is necessary for the definition to be predicated of everything of which the name is predicated, and, further, to be convertible with them, if the assigned definition is going to be special. When disestablishing, on the other hand, it is no longer necessary to prove the universal; for it is enough to prove that the account is not true of any one of the things falling under the name. Also, even if it is necessary to disestablish it universally, it is not necessary even then for it to be convertible before disestablishing it; for it is enough when disestablishing universally to prove that the account is predicated of none of the things of which the name is predicated. But it is not necessary to prove contrariwise that the name is predicated of things of which the account is not predicated. Further, even if it belongs to everything that falls under the name, but not to them alone, the definition is done away with.

It is similar too where special affection and kind are concerned; for in both cases it is easier to disestablish than to establish. Where a special affection is concerned, then, this is evident from what has been said; for a special affection is for the most part

198. 148a14–22.

assigned in combination,[199] so that it is possible to disestablish it by doing away with [only] one part, while when establishing it is necessary to deduce all of them. And it is fitting to state pretty much all of the remaining points about definition about a special affection as well; for a person establishing a special affection must prove that it belongs to all of the things that fall under the name, while when disestablishing it is enough to prove that it does not belong to one; and even if it does belong to all, but not only to them, it that way too it is disestablished, as was said in the case of definition.

Where the kind is concerned, [it is clear] that there is necessarily only one way to establish it, to prove that it belongs in every case, while it is disestablished in two ways; for if in fact it has been proved to belong in none and also if it has been proved not to belong in some, what was said initially is done away with. Further, when establishing, it is not enough to prove that it belongs, but rather one must also prove that it belongs as kind. When disestablishing, on the other hand, it is enough to prove that it does not belong either in some or in all cases. And it seems that, just as in other areas it is easier to destroy than to produce, so, in these sorts of cases too, disestablishing is easier than establishing.

In the case of a coincident, the universal is easier to disestablish than to establish; for when establishing, one must prove that it belongs in every case, while when disestablishing, it is enough to prove that it does not belong in one. In the case of the particular, it is the reverse: it is easier to establish than to disestablish; for when establishing, it is enough to prove that it belongs in one case, while when disestablishing, one must prove that it belongs in none. **155ᵃ1**

It is evident too why a definition is the easiest of all to disestablish; for since in it many things are assigned, many things are stated, and the more things it is based on, the faster a deduction comes about; for error is likely to occur more in many things than in few. Further, a definition also admits of being attacked through the others; for if the account is not special, or if what is assigned is not the kind, or if something in the account does not belong, the definition is done away with. Against the others, by contrast, neither the things derived from the definition nor all the rest can be used to mount an attack; for only the ones against a coincident are common to all those mentioned. For each of those mentioned must belong to the thing. But if the kind does not belong as something special, the kind is not yet done away with. Similarly too, it is not necessary for a special affection to belong as a kind, or for a coincident to belong as a kind or a special affection, but rather merely to belong. So it is impossible to attack one lot on the basis of the other, except in the case of definition. It is clear, then, that a definition is easiest of all to do away with but the most difficult to establish; for there one must deduce all these; for one must deduce that the things mentioned belong, that what is assigned is a kind, and that the account is special, and further, beyond this, that the account indicates the essence, and has done this correctly.

199. 132ᵃ10–16.

Among the others, the special affection is most like this; for it is easier to do away with because for the most part it is based on more things, and more difficult to establish, because one must infer more things, and in addition, prove that it belongs to and is counterpredicated of the thing at issue.

A coincident is the easiest of all to establish; for in the case of the others, one must prove not merely that it belongs, but also that it belongs in the requisite way, while in the case of a coincident it is enough to prove that it merely belongs. To disestablish it, on the other hand, is the most difficult, because the fewest things are assigned in it; for it is not additionally signified in the coincident in what way it belongs. So in the other cases there are two ways to do away with them, either by proving that they do not belong or that they do not belong in the requisite way, while in the case of a coincident there is no doing away with it except by proving that it does not belong.

The topics through which we will be well equipped to argue dialectically in relation to each of the problems have now been pretty much adequately enumerated.

155b1

BOOK 8

8.1
How to Ask Dialectical Questions (1)

After this we must speak about arrangement, that is, the way one should ask questions. A person who is going to frame questions must, first, find the topic from which to make his attack; second, frame the questions, and arrange them one by one for himself; it remains, third, to ask these, this time to someone else. Up to the point of finding the topic, then, the philosopher's investigation and the dialectician's are similar, but then arranging these things and framing questions is special to the dialectician; for everything of this sort is in relation to someone else. But the philosopher, who is investigating by himself, does not care whether, though the things through which his deduction proceeds are true and known, the answerer does not grant them (because they are close to what was initially at issue, and he foresees what is going to result), but rather the philosopher is presumably eager for his claims to be as known and as close to what is at issue as possible; for it is from things of this sort that scientific deductions proceed.

The things on the basis of which topics must be taken, then, were stated previously.[200] We must now discuss arrangement and the framing of questions, determining which premises, beyond the necessary ones, must be obtained. The ones said to be necessary are the ones through which a deduction proceeds. The ones to be obtained beyond these are of four sorts. They are either for the sake of an induction to assign the

200. Books 2–7.

universal, to add bulk to the argument, for the concealment of the conclusion, or to make the argument more perspicuous. Beyond these there are no premises one must obtain, but rather it is through them that one must develop [their arrangement] and frame one's question. The ones for concealment are for the sake of competition.[201] But since every business of this sort is in relation to someone else, it is necessary to make use of these too.[202]

One must not propose the necessary premises through which a deduction directly proceeds, but rather one must stand off as far above them as possible. For example, do not expect to obtain that the science of contraries is the same, if that is what one wishes to obtain, but rather that it is of opposites; for if he grants this, it can be deduced that the science of contraries is the same too, since contraries are opposites, while, if he does not, one must obtain it by induction, by proposing premises about particular contraries. For one must obtain the necessary premises either by deduction or by induction, or else some by induction, others by deduction (but if they are extremely evident beforehand, even they themselves may be proposed); for both in standing off and in induction it is less clear what is going to result, and at the same time it is still open to one to propose the useful premises themselves if one cannot obtain them in those ways.

Those beyond the ones mentioned must be obtained for the sake of these [necessary ones], and each must be used in this way: when arguing inductively, [argue] from particular to the universal, and from the known to the unknown (for the known is what is in accord with perception, whether unconditionally or to most people); but, when concealing, pre-deduce the things through which the deduction of what was initially at issue comes about, and obtain as many of these as possible. And this would come about if one deduced not only the necessary premises, but also some of those useful for obtaining them. Further, do not state the conclusions, but instead state them as a body later on; for this way one would stand farthest off from what was posited initially.

To speak in universal terms, a person who is obtaining answers in a concealed way must so ask questions that when the whole argument has been framed as questions and he states his conclusion, the why is looked for [by the answerer]. But this will most of all come about in the way just stated; for if only the ultimate conclusion is stated, it will be unclear how it follows, because the answerer does not foresee what it follows from, if the prior deductions were not fully articulated. And the deduction of the conclusion would be least fully articulated if we propose not the premises of that deduction, but rather those in virtue of which that deduction comes about.

It is also useful not to obtain the claims from which the deductions proceed as a continuous series, but rather alternating the claims related to one conclusion with

201. $159^{a}26$–36, $161^{a}37$–$^{b}1$, *SE* $165^{b}10$–11.
202. *SE* $183^{b}1$–6.

those related to the other; for if the ones proper [to the deduction bearing on the posit] are put next to each other, what results from them will be more easily foreseen.

Also, in those cases that admit of it, one should obtain the universal premise by means of a definition that applies not to the things at issue themselves, but rather to their co-ordinates. For people fallaciously deceive themselves, when the definition of the co-ordinate has been obtained, that they have not conceded the universal—for example, if what one must obtain is that an angry person desires revenge, and it could be obtained that anger is a desire for revenge because of apparent contempt; for it is clear that once this has been obtained we would have the universal we wanted. On the other hand, it often happens to those who propose [one that applies to] the things at issue themselves that the answerer refuses it because he is more ready with an objection to it—for example, that an angry person does not desire revenge; for we get angry with our parents, but do not desire revenge. Presumably, his objection is not sufficient; for in the case of some people, merely paining them or making them regret is a sufficient revenge. Nonetheless, as regards not seeming to be unreasonably refusing what is proposed, he has something persuasive [to say]. But in the case of the definition of anger, it is not equally easy to find an objection.

Further, propose something as if not proposing it because of itself but for the sake of some other proposals; for people are on the lookout for things that are useful against the posit. And, to speak simply, make it as unclear as possible whether one wishes to obtain what one proposes or its opposite; for if it is unclear which one is useful to the argument, people will more readily accept what seems to be so to them.

Further, obtain answers through similarity; for it is both persuasive and better hides the universal. For example, arguing that since the science as well as the ignorance of contraries is the same, so too the perception of contraries is the same; or—the reverse—since the perception is the same, the science is too. This is similar to induction, but certainly not the same; for there one obtains the universal from the particulars, while in the case of similar things what one obtains is not the universal under which all the similar things fall.

Also, one must sometimes bring an objection against oneself; for answerers have a minimally suspicious attitude toward those who seem to be arguing dialectically in a just way. It is also useful to add that such-and-such is customary and a saying; for people hesitate to disturb what is customary if they have no objection to offer, and at the same time, since they make use of such things themselves, they guard against disturbing them.

Further, do not be eager, even if the point is an altogether useful one; for people are more likely to resist those who are eager. Also, proposing something as if in a comparison;[203] for if something is proposed because of something else and not because it is useful because of itself, people more readily accept it. Further, do not propose the thing itself that is to be obtained, but something from which it follows of

203. *Rh.* 1393b3–8.

necessity; for people more readily concede it because it is not equally evident what is going to follow from this, and once the latter has been obtained, the former has also.

Also, wait till almost the last moment to ask for what one most wishes to obtain; for it is the first things that people most refuse, because most questioners state first the things they are most eager about. Against some people, these are the things to propose first; for hagglers most readily concede the first things, if it is not completely evident what will result, but haggle toward the end. It is the same way too with people who think themselves incisive answerers; for after they have accepted most points, toward the end they become extremely subtle on the presumption that things do not follow from what has been proposed. They accept things off-handedly, trusting in their talent and supposing that they will not suffer any loss.

Further, lengthen the argument and throw in things that are of no use to it, like **157ª1** those who draw false diagrams;[204] for when there are many things, it is unclear in which one the falsehood lies. That is also why questioners escape notice by putting forward in a hole-and-corner way things that would not be accepted if proposed by themselves.

For concealment, then, use the things mentioned, while for ornamentation, use induction and the division of things that are akin. What sort of thing induction is clear. Division is this sort of thing—for example, one science is better than another either by being more exact[205] or by being the science of better things;[206] or, of the sciences, some are theoretical, some practical, and some productive. For each of these sorts of things ornaments the argument, though they are things it is not necessary to state to obtain the conclusion.

For perspicuousness adduce paradigms[207] and comparisons, and the paradigms must be relevant and drawn from things known ("as Homer says," not "as Choerilus says"); for in this way what is proposed would be more perspicuous.

8.2
How to Ask Dialectical Questions (2)

In arguing dialectically, use deduction with those skilled in dialectic more than with ordinary people; contrariwise, use induction more with ordinary people. This was also spoken about previously.[208]

In some cases, it is possible when doing an induction to frame the universal as a question. In others, however, this is not easy because a common name has not been established for all the similar cases, but rather, when the universal [premise] must be

204. See *SE* $171^{b}12$–16.
205. *APo*. $87^{a}31$–37.
206. *DA* $402^{a}1$–4, *Met*. $983^{a}4$–$983^{a}11$, *NE* $1141^{b}2$–3.
207. *Rh*. $1356^{b}13$–15.
208. $105^{a}16$–19.

obtained, they say, "it is this way in all cases of this sort." But this is one of the most difficult things, to determine which of the cases proposed are of the relevant sort and which are not. Also, by means of this people often cheat each other in arguments, some saying that things are similar when they are really not, others disputing the similarity of things that are similar. That is why one must try to make a name oneself that will apply to all the things of the relevant sort, so that it will neither be open to the answerer to dispute, saying that what is being introduced is not said of things in a similar way, nor to the questioner to quibble, saying that it is said of things in a similar way, since many that are not said of things in a similar way appear to be said of them in a similar way.

When one does an induction from many cases and someone does not grant the universal [premise], then it is just to demand an objection. But when one has not said oneself in which cases it holds, it is not just to ask in which cases it does not hold; for one must previously have done an induction to demand an objection in this way. Also, one must expect him to bring objections not to the thing proposed alone, unless it is the one and only thing of the relevant sort, as two is the only even number that is prime; for the objector must either bring his objection against another case or say that this is the only case of the relevant sort.

Against objectors to the universal [premise] who bring their objection not against the thing itself but against some homonym of it, for example, that someone could have a color, a foot, or a hand that was not his own (for a painter could have a color and a cook a foot that was not his own)—in cases of this sort, then, one must draw distinctions when framing questions; for if the homonymy remains concealed, the objector will seem to have objected well to the premise.

If, on the other hand, the answerer blocks the question by objecting, not to a homonym, but to the thing itself, subtract the point to which the objection is made, proposing the remainder and making it the universal, until one obtains what is useful. For example, in the case of forgetfulness, that is, of having forgotten; for people do not want to grant that someone who has lost scientific knowledge has forgotten it (because if the thing at issue changes, he has lost scientific knowledge, but has not forgotten). Subtracting, then, what the objection applies to, one must state the remainder—for example, if, when the thing at issue remains as it is, someone loses his scientific knowledge, it is because he has forgotten it. It is the same way too in the case of those who object to the statement that to a greater good a greater bad is opposed; for they propose the fact that to health, which is a lesser good than good condition, a greater bad is opposed; for disease is a greater bad than bad condition. In this case too subtract what the objection applies to; for when it is subtracted, the answerer would more readily accept the remainder, for example, that to a greater good a greater bad is opposed unless one brings the other along with it, as good condition does health.

Do this not only if the answerer has made an objection, but also if, without making an objection, he has refused [the universal premise], because he foresees something of

this sort. For when what his objection applies to is subtracted, he will be compelled to accept it, because he does not foresee in the remainder any case of which it does not hold; and, if he does not accept the premise, when one demands an objection, he will not have any to give. Premises of this sort are those that are false in some cases and true in others; for it is in their case that it is possible to leave a true remainder by subtracting.

But if, when one proposes a premise based on many cases, he brings no objection, he is expected to accept it; for a premise is dialectical if it holds in many cases and there is no objection to it.

When the same thing admits of being deduced both without [reduction to] the impossible and through [reduction to] the impossible, then, although when demonstrating it makes no difference whether it is deduced in one way or the other, when arguing dialectically with someone else, one should not use the deduction through the impossible. For against someone who has deduced without the impossible, it is not possible to dispute. On the other hand, when he has deduced the impossible thing, unless it is extremely evident that it is false, people say that it is not impossible, so that questioners do not get what they wish. **158^{a}1**

One must also propose whatever premises hold in many cases and to which either there is no objection at all or none that is visible on the surface; for if people cannot see cases in which something does not hold, they accept it as true.

But one should not make the conclusion into a question. Otherwise, if the answerer shakes his head in refusal, it seems that no deduction will come about. For often, even when one does not ask the conclusion, but puts it forward as what follows, people refuse it, and by doing this they will seem not to be refuted to those who are not able to see that it follows from what has been accepted. When, then, one asks it without even saying that it follows and the answerer refuses it, it seems as if no deduction has come about at all.

It does not seem, however, that every universal question is a dialectical premise—for example, What is a human being? or, In how many ways are things said to be good? For a dialectical premise is one to which it is possible to answer yes or no. But to the ones just mentioned it is not possible. That is why questions of this sort are not dialectical, unless one assigns the definition oneself or goes through the ways it is said in stating them—for example, Is it not the case that things are said to be good either in this way or that? For to things of this sort it is easy to answer either by affirming or denying. That is why one must try to propose premises of this sort in this way. At the same time, it is also presumably just to inquire from the answerer in how many ways things are said to be good, when, though one has oneself determined them and proposed them, he concedes none of them.

Someone who spends a long time asking questions on a single line of argument is getting answers in a bad way. For if the one being questioned is answering, this is clear, because he is asking many questions or the same ones repeatedly, so that he is either babbling or has no deduction (for every deduction is composed of few things);

on the other hand, if he is not answering, it is again clear, because he does not criticize him or cut off discussion.

8.3
Hypotheses Difficult to Attack

The hypotheses it is difficult to attack and those easy to maintain are the same. And the things that are first by nature and the ones last are of this sort. For the first ones require definition, while the last ones are inferred by means of many steps by anyone wishing to take a continuous series from the first ones (otherwise the attacks appear sophistical); for it is impossible to demonstrate anything without starting from the proper starting-points and making connections as far as the last ones. Answerers neither think it requisite for things to be defined nor, if the questioner does define them, do they take heed. Yet if it has not been made evident what exactly the thing proposed is, it is not easy to attack it. But this sort of thing happens most of all
158b1 concerning the starting-points; for other things are proved through them, but they do not admit of being proved through other things; rather, it is necessary to know each thing of this sort by means of a definition.

Also difficult to attack are things that lie extremely close to the starting-point; for it is not possible to equip oneself with many arguments against these, since there are few intermediate steps between it and the starting-point, through which it is necessary for what comes after these to be proved.

Among definitions, however, the most difficult of all to attack are those in which names have been used of such a sort that it is, first, unclear whether they are said of things simply or in many ways, and, second, it is not known whether they have been used by the definer in their literal sense or metaphorically. For because they lack perspicuousness, they do not have points of attack; and because one is ignorant as to whether it is because of their being said of things metaphorically that they are like this, they do not have a point of criticism.

In general, any problem, when difficult to attack, must be supposed either to require definition, to contain things said in many ways or metaphorically, or to be not far from the starting-points, or because it is not evident to us in the first place in which of ways just mentioned our puzzlement is produced; for when the mode is evident, it is clear that we must either define, distinguish, or be equipped with the intermediate premises; for it is through these that the last ones are proved.

And with many posits, if the definition is not correctly assigned, it is not easier to argue dialectically and attack them—for example, whether one thing has one contrary or several. But when contraries have been defined in the appropriate way, it is easy to infer whether it is possible for there to be several contraries of the same thing or not. And it is the same way in the other cases too.

It seems that in mathematics too it is not easy for a diagram to be drawn in proof of some things because of omission of a definition—for example, that the line cutting the plane parallel to a side divides both the line and the area similarly. When the definition is stated, what is said is evident at once; for the areas and the lines have the same reciprocal subtraction,[209] and this is the definition of same ratio. The first elements are easily proved when the definitions (for example, what a line is and what a circle is) are accepted, except that the arguments that can be used to attack each of these are not many, because there are not many intermediates. But if the definitions of the starting-points are not accepted, this is difficult to do, perhaps wholly impossible. Similar things hold in the case of [dialectical] arguments.

We should not overlook, then, when a posit is difficult to attack, that it is because it has one of the affections just mentioned. But when it takes greater work to argue dialectically for the claim (that is, the premise) than for the posit, one might be puzzled as to whether such things must be accepted or not. For if he will not accept it, but will expect one to argue dialectically for it as well, he will be prescribing something greater in place of what was initially at issue, while if he will accept it, one will be persuading on the basis of what is less persuasive. If, then, the problem must not be made more difficult, he must accept it, while if the deduction must proceed through better-known things, he must not accept it. Or else: by someone who is learning, it must not be accepted if it is not better known, while by someone who is training, it must be accepted only if it appears true. So it is evident that one must not expect to grant acceptance to a questioner and to a teacher in the same way.

8.4
How to Answer Dialectical Questions (1)

As for how one must frame questions and arrange them, what has been said is pretty much enough.

Where answering is concerned, one must first determine what the work of a good answerer, as of a good questioner, consists in. It belongs to a questioner to lead the argument in such a way as to make the answerer state the least acceptable of the beliefs that are necessary because of the posit, while it belongs to an answerer to make it appear that it is not because of him that anything impossible or unacceptable appears to result, but because of the posit; for agreeing at first to what one must not agree to is a distinct error from not defending properly what has been agreed to.

209. If A is a larger magnitude than B, repeatedly subtract B from A until the remainder R_1 is less than B. Subtract R_1 from B until a remainder R_2 less than R_1 is reached. Continue in the same way. Stop if and when a fit is reached. If C is a larger magnitude than D, the pair <A, B> has the same reciprocal subtraction as the pair <C, D>, if the number of such subtractions is the same for each. If the procedure does not terminate, the magnitudes are incommensurable. Aristotle applies the procedure to parallelograms and their sides.

8.5
How to Answer Dialectical Questions (2)

But these things are indeterminate for those who produce arguments for the sake of training and examination. For the aims of teachers and learners are not the same as those of competitors, nor those of the latter as those who spend time together for the sake of investigation; for a learner must always accept the things that seem true; for no one tries to teach a falsehood. Among competitors, a questioner must at all events appear to be producing some effect, while the answerer must appear not to be affected at all. In the case of dialectical meetings, by contrast, for those who produce arguments for the sake, not of competition, but of examining and investigating, it has never been fully articulated what the answerer must aim at, or what sorts of things he must grant and what sorts he must not grant to correctly defend the posit. Since, then, nothing has been handed down by others, we must try to say something ourselves.

It is necessary for the answerer to take up the argument by accepting a posit that is either acceptable, unacceptable, or neither, and one that is acceptable or unacceptable either unconditionally or in a definite way—for example, to a certain person, whether himself or someone else. It makes no difference, however, in whichever way the posit is acceptable or unacceptable; for the way of answering well, of conceding or not conceding what is asked, will be the same.

If the posit is unacceptable, the conclusion that results must necessarily be acceptable, and if it is acceptable, unacceptable; for the questioner always tries to conclude the opposite of the posit. And if what is proposed is neither unacceptable nor acceptable, the conclusion will also be of this sort. And since a person who deduces correctly demonstrates the problem[210] from more acceptable and better-known things, it is evident that if what is proposed is unconditionally unacceptable, the answerer must grant neither what does not seem unconditionally to be the case nor what seems to be the case but less so than the conclusion. For if the posit is unacceptable, the conclusion is acceptable, so that all the things obtained must be acceptable, and more acceptable than the thing proposed, if it is through things that are better known that less well-known ones are going to be inferred. So, if one of the things asked is not of this sort, the answerer should not accept it.

If the posit is unconditionally acceptable, it is clear that the conclusion is unconditionally unacceptable. The answerer must accept, then, both all the things that seem so and whatever things do not seem to be so, but are less acceptable than the conclusion; for then it would appear to be argued dialectically in a sufficient way.

It is the same way if the posit is neither acceptable nor unacceptable; for in this case too, the answerer must grant both everything that appears so, and whatever

210. 104b1–17.

things do not seem to be so, but are more acceptable than the conclusion; for in this way the resulting arguments will be more acceptable.

If, on the other hand, what is proposed is unconditionally acceptable or unacceptable, it is with respect to things that seem so unconditionally that he must make the comparison.[211] But if what is proposed is acceptable or unacceptable, not unconditionally, but to the answerer, it is with respect to what seems to be so to himself or does not seem to be so that he should judge what to accept or not accept.

If the answerer is defending someone else's belief, it is clear that he must accept or refuse each thing by looking to that other person's thought. That is why those who introduce the beliefs of others—for example, that the same thing is good and bad, "as Heraclitus says"—do not grant that contraries cannot belong to the same thing at the same time, not because of believing this themselves, but because according to Heraclitus this is what one must say.[212] This is also what those people do who take over posits from each other; for they aim at saying what those who posited it would say.

8.6
How to Answer Dialectical Questions (3)

It is evident, then, what the answerer must aim at, whether what is proposed is acceptable unconditionally or to a certain person. But since everything asked must be either acceptable or unacceptable or neither, and what is asked must be either relevant to the argument or not relevant to the argument, if it seems to be so, and is not relevant to the argument, having said that it seems to be so, he must grant it, while if it does not seem to be so, and is not relevant to the argument, he must accept **160ª1** it, but indicating in addition that it does not seem to be so, as a precaution against [a charge of] simplemindedness.

If it is relevant to the argument, and seems to be so, he must say that, though it seems to be so, it is too close to what was initially at issue, and that what is proposed is done away with if this is accepted.

If the claim is relevant to the argument but too unacceptable, he should say that, though the conclusion results if it is accepted, what is proposed is too simpleminded.

If it is neither unacceptable nor acceptable, if it has no relevance to the argument, he must grant it without drawing distinctions, while if it is relevant to the argument, he must indicate in addition that what was posited initially is done away with by it. For in this way the answerer will appear not to be affected at all because of what he himself does, if he accepts each thing with foresight, and the questioner will bring to pass his deduction, since everything more acceptable than the conclusion is granted to him.

211. I.e., between the relative costs and benefits, measured in terms of things believed unconditionally, of accepting or refusing a premise.
212. *Met.* $1005^{b}23$–26.

Those, on the other hand, who try to deduce from things more unacceptable than
15 the conclusion, clearly do not deduce correctly, which is why one should not accept what is posited [and grant it] to the questioners.

8.7
Answering Questions That Lack Perspicuousness or Are Said in Many Ways

One must also reply in the same way to questions that lack perspicuousness or that are said in many ways. For since it is granted to the answerer who does not understand to say, "I do not understand," and, if the question is said in many ways, not to have of
20 necessity to agree or decline, it is clear, first, that if what is said is not perspicuous, he must not hesitate to say that he does not comprehend it; for in many cases, as a result of conceding what is not asked perspicuously, he would confront something difficult. But if what is said is something known, and, though it is said in many ways, is true or
25 false in all of them, he should accept or refuse it unconditionally. On the other hand, if it is false in one case and true in another, he should indicate in addition that it is said in many ways, and that it is false in the one and true in the other; for if he draws this distinction later on, it will be unclear whether he also saw the ambiguity initially. But if he did not see the ambiguity earlier, but accepted looking at one of the two
30 ways it is said, he must say to a questioner leading him to the other one, "I did not grant it looking to that one but to the other of them"; for if there are several things falling under the same name or account, disputation easily arises. But if what is asked is perspicuous and simple,[213] he must answer either "yes" or "no."

8.8
Answering Particular versus Universal Questions; Haggling

35 Since every deductive premise is among those the deduction is composed of or else is for the sake of one of them (and it is clear when someone is obtaining it for the sake of another one, because of his asking for several similar things; for it is either through induction or through similarity[214] that people for the most part obtain the universal), the answerer must accept all the particular cases, insofar as they are true
160b1 and acceptable, but should try to bring an objection against the universal; for to prevent the argument without a real or seeming objection is haggling. If, then, he does not grant the universal when it appears so in many cases, though not having an objection, it is evident that he is haggling. Further, if he has not even got it in him

213. I.e., the contrary of being said in many ways.
214. 156b14–17.

to counterargue that it is not true, he would seem all the more to be haggling. (And yet even this is not enough; for we have at our disposal many arguments against [acceptable] beliefs that are difficult to resolve—for example, Zeno's argument[215] that it is not possible to move or to traverse the stadium, but one must not, because of this, refuse to accept their opposites.) If, then, though neither having an objection nor being able to counterargue, he does not accept, it is clear that he is haggling; for haggling in arguments is answering in a way beyond the ways just mentioned, that is, in a way destructive of deduction.

8.9
Practicing on Oneself; Unacceptable Hypotheses

To uphold a posit or a definition, one must try developing counterarguments to it by oneself ahead of time; for it is clear that the things one must oppose are the ones on the basis of which those obtaining answers do away with what was proposed.

One must beware of upholding an unacceptable hypothesis. And there are two ways it could be unacceptable; for it could be so by being one from which saying absurd things follows (for example, if someone were to say that everything or nothing is in movement) or by being what someone with a worse character would choose, or what is contrary to our wishes (for example, that pleasure is the good, or that doing injustice is better than suffering injustice); for on the supposition that these are not things one says merely for the sake of argument but the things that seem so to you, people hate you.

8.10
Resolving Arguments That Deduce a Falsehood

As for arguments that deduce a falsehood, resolve them by doing away with the thing through which the falsehood comes about; for it is not the person who does away with any thing whatever that resolves it, not even if what is done away with is false. For the argument might contain several falsehoods—for example, if someone obtained that the person seated is writing, and that Socrates is seated; for it follows from these that Socrates is writing. When "Socrates is seated" is done away with, the argument is no closer to being resolved, and yet the claim is false. But it is not by depending on it that the argument is false; for if someone happened to be seated but not writing, the same resolution will no longer fit such a case. So it is not this that must be done away with, but rather that the person seated is writing; for not every seated person is writing. The person, then, who does away with what the falsehood

215. *Ph.* 233ᵃ21–31, 6.9.

depends on has entirely resolved the argument, and it is the person who knows that the argument depends on it who knows the resolution (as in the case of drawing false diagrams[216]). For it is not enough to object, not even if what is done away with is false, but one must also demonstrate why it is false; for this way it would be evident whether or not he makes his objection with foresight.

161ᵃ1 There are four ways to prevent an argument from reaching a conclusion: by doing away with what the falsehood depends on; by stating an objection to the questioner (for often he has not resolved anything, yet the one obtaining answers is not able to lead him any further); third, objecting to the questions asked (for it may happen that what the questioner wishes does not come about on the basis of the questions asked, because they have been framed incorrectly, though when something is added the conclusion does come about). If, then, the questioner cannot advance any further, the objection would be against the questioner, while, if he can, against his questions. The fourth and worst sort of objection is the one relating to the time (for some people raise an objection of this sort, that it would take longer to dialectically argue against than the present discussion allows).

Objections, then, as we said, come about in four ways. But only the first of those mentioned is a resolution, while the remaining ones are sorts of preventions and impediments to conclusions.

8.11
Criticism of Arguments as Such versus When Framed as Questions

Criticism of an argument intrinsically as an argument is not the same as criticism of it when it is framed as questions. For often the person questioned is responsible for the argument having not been dialectically argued correctly, because he does not concede the things from which it was possible to dialectically argue correctly against the thesis; for it is not up to one of two partners alone to ensure that their common work is correctly accomplished. Sometimes, then, it is necessary to attack the speaker not his posit: when the answerer is on the lookout for things that go contrary to the questioner and is abusive besides. By haggling, at all events, people make their discussions competitive not dialectical.

Further, since arguments of this sort are for the sake of training and examining, not of teaching, it is clear that not only true but also false conclusions must be deduced, and not always through truths but sometimes also through falsehoods; for often, when a truth has been posited, it is necessary for the dialectician to do away with it, so that he must use falsehoods as a premise. And sometimes, even when a falsehood has been posited, he must do away with it through falsehoods; for there is nothing to prevent things that are not so from seeming to be more so to someone

216. *SE* 171ᵇ12–16.

than things that are true, so that if the argument comes about from things that seem to be so to him, he will be more persuaded than benefited.

Anyone who is going to change the course of an argument correctly, however, must change it in a dialectical way, not in a contentious way, just as the geometer must do so in a geometrical way, regardless of whether the conclusion is false or true. (What sort of deductions are dialectical was stated previously.[217])

Since it is a bad partner who impedes the common work, it is clear that it is so in argument as well. For there is also something common proposed[218] in arguments, except in the case of competitive ones. In these it is not possible for both to achieve the same end; for there cannot be more than one winner. It makes no difference whether one does this by answering or by questioning; for the person who questions in a contentious way argues dialectically in a bad way, and so does the answerer who will neither grant what is evident nor admit to understanding what the questioner can possibly wish to obtain with his question.

It is clear, then, from what has been said that an argument intrinsically as such must not be criticized in the same way as a questioner; for there is nothing to prevent the argument's being bad, though the questioner has argued dialectically as well as possible with the answerer. For, against hagglers, one is perhaps simply not able to produce such deductions as one wishes, but only such as one can.

Since it is indefinite when human beings assume contrary things and when they assume what was initially at issue (for often when talking to themselves they say contrary things, and, having refused something earlier, grant it later on—which is why, when they are asked for contraries and when they are asked for what was initially at issue, they often grant these), bad arguments necessarily come about. The one responsible [in these cases] is the answerer who at certain moments does not grant some things but at other moments grants others of the same sort.

It is evident, then, that questioners and arguments must not be criticized in the same way.

Of an argument as intrinsically such, there are five criticisms. First, from the premises asked, neither what was proposed nor anything else at all is concluded, since all or most of the premises in which the conclusion lies are either false or unacceptable, and the conclusion does not come about either when some premises are subtracted or when some are added or when some are subtracted and others added. Second, if it is not against the posit that a deduction comes about (from the sorts of premises and in the way mentioned just previously). Third, if a deduction comes about with certain premises added, but these are worse than the ones asked for and less acceptable than the conclusion. Again, if it comes about with certain premises subtracted; for sometimes more premises are assumed than are necessary, so that it is not through them that the deduction comes about. Further, if it is from premises

217. 100^{a}29–^{b}23, 159^{a}25–34.

218. Reading τὸ προκείμενόν ἐστι.

more unacceptable and less persuasive than the conclusion; or if it is from premises that are true but require more work to demonstrate than the problem does.

One must not require the deductions of all problems to be equally acceptable and persuasive; for simply by nature some objects of inquiry are easier and others more difficult, so that if one has inferred from the most acceptable premises possible, one has argued dialectically in the correct way. It is evident, then, that the same criticism also does not apply to an argument in relation to the problem at issue and an argument intrinsically as such; for there is nothing to prevent an argument from being intrinsically blameworthy but praiseworthy in relation to a problem; or again, **162^a1** conversely, intrinsically praiseworthy but blameworthy in relation to the problem: when there are many premises both acceptable and true from which it is easily concluded. It is possible too that an argument that reaches a conclusion may sometimes be worse than one that does not reach a conclusion: when the first is concluded from simpleminded premises (the problem not being of that sort), while the second needs additional premises, but of the sort that are acceptable and true, and it is not in the additional ones [by themselves] that the argument lies. As regards those that reach a conclusion through falsehoods, it is not just to criticize them; for a falsehood must always be deduced through falsehoods, while it is sometimes possible for a truth to be deduced even through falsehoods. This is evident from the *Analytics*.[219]

When the argument stated is a demonstration of something, if there is something else that is not related in any way to the conclusion, it will not be a deduction of that. And if it were [made] to appear to be one, it would be a sophism, not a demonstration. {A *philosophêma* is a demonstrative deduction; an *epicheirêma* is a dialectical deduction; a sophism is a contentious deduction; and an *aporêma* is a dialectical deduction of a contradiction.}[220]

If something is proved from premises both of which seem so, but do not seem equally so, there is nothing to prevent what is proved from seeming more so than each singly. But if one premise were to seem so and the other to seem neither so nor not so, or if one were to seem so and the other not so, then if these are equal, [the conclusion] would be equally so or not so, but if one of the two is more, it will follow along with the one that is more so.

There is also the following error regarding deductions: when someone proves something through a longer series of steps, though it could be proved through fewer ones that actually belong in the argument. For example, if to prove that one belief is more [a belief] than another, someone were to assume the following: a thing-itself is most of all [that thing], there is a truly believable-itself, and so it will be more [that thing] than the particular ones; but what is said in relation to the more is more [that

219. *APr*. 2.2, *APo*. 78^a6–13.

220. Probably inauthentic. Elsewhere a *philosophêma* seems to be a work of philosophy (*Cael*. 279^a31–32) or a puzzle that has become a standard philosophical one (294^a19–20), while an *aporêma* seems to be simply a puzzle (*APr*. 71^a29, *APo*. 92^a29, *Ph*. 211^a10–11, *GC* 327^b32, *Met*. 1004^a34, 1011^a6, 1077^a1).

thing]; but again there is a true believable-itself, which will be more exactly [that thing] than the particular ones. He assumed the existence of a true believable-itself and that each thing-itself is most of all [that thing], so [as to prove] that this true belief is more exactly [a belief than another]. What, though, is the fault? Or is it that what the argument depends on makes hidden the cause?

8.12
Clear and False Arguments

An argument is clear in one way, which is also the most commonly used one, if it reaches a conclusion in such a way that no further questions are needed; in another way, which is also the one most of all said to be such, when the premises obtained are the ones it is necessary for the conclusion to be deduced from, and it is concluded through conclusions; in a further way, if anything[221] missing is extremely acceptable. **$162^{b}1$**

An argument is called "false" in four ways: one way is when it appears to reach a conclusion but does not reach a conclusion (this is called a "contentious deduction").[222] Another is when it reaches a conclusion, but not in relation to the thing proposed (which is just what happens most in those leading to impossibility). Or it reaches a conclusion in relation to what is proposed, but not in accord with the methodical inquiry proper to it. And this is when it appears to be medical but is not medical, or geometrical but is not geometrical, or dialectical but is not dialectical, whether what results is true or false. Another way is if it reaches a conclusion through falsehoods. And its conclusion, though it will sometimes be false, will sometimes be true; for a falsehood is always inferred through falsehoods, but it is possible for a truth to be inferred even though not from truths, as was also stated previously.[223]

An argument's being false is an error of the arguer rather than of the argument (and it is not even always of the arguer, but only when he is not aware of it), since, as intrinsically such, we approve of it more than of many true ones, if from what seems most of all to be so it does away with some truth. For an argument of this sort is a demonstration of other truths; for one of the things proposed must not be absolutely true, so that it will be a demonstration of this. But if a true conclusion were to be reached through false and very simpleminded premises, it would be worse than many that deduce a falsehood, and it might be of this sort even if reaching a false conclusion.

So it is clear that the first step in investigating an argument as intrinsically such is to see whether it reaches a conclusion, second, whether this is true or false, third, from what sorts of premises. For if it is from false but acceptable premises, it is a logico-linguistic argument; if from true but unacceptable ones, it is a bad one; if

221. Reading τι.
222. $100^{b}23–25$.
223. $162^{a}9–11$.

from false and extremely unacceptable ones, it is clear that it is a bad one, either unconditionally or in relation to the thing at issue.

8.13
Asking for What Was Initially at Issue; Asking for Contraries

How a questioner asks for what was initially at issue and for contraries has been stated in accord with truth in the *Analytics*,[224] and must now be stated in accord with belief.

People appear to ask for what was initially at issue in five ways. The most evident and the first is if someone asks for the very thing that needs to be proved. In the case of the very thing, this is not easy to conceal, but in the case of synonyms and in those cases in which a name and an account signify the same thing, it is easier. The second is when someone needing to demonstrate a particular asks for a universal—for example, trying to demonstrate that the science of contraries is one, he expects to obtain that that the science of opposites in general is one; for he seems to be asking for what he needed to prove by itself, together with several other things. Third, if when it is proposed that a universal be proved, someone were to ask for a particular—for example, when it is proposed that the science of all contraries is one be proved, he expects to obtain this about these particular contraries; for this person too seems to be asking for what, together with other things, he needed to prove separately by itself. Again, if someone, dividing it up, asks for the problem—for example, if someone, needing to prove that medicine is the science of healthy and diseased, were to expect to obtain each of these separately. Or if someone were to expect to obtain one or other of the things that of necessity follow along with each other—for example, that the side is incommensurable with the diagonal, when he must demonstrate that the diagonal is incommensurable with the side.

People ask for contraries in the same number of ways as they do for the starting thing. For the first is if someone were to ask for an opposed assertion and denial; second, for contraries by an antithesis—for example, [asking whether] the same thing is good and bad. The third is if someone who expected to obtain the universal were to ask for its contradictory in the case of particulars (for example, if having obtained that the science of contraries is one, he were to expect to obtain that there is a science of healthy and a different science of diseased). Or if, having asked for the latter, he were to try to obtain the contradictory in the case of the universal. Again, if someone were to ask for the contrary of what results of necessity through the things proposed, and even if he were not to [try to] obtain the [pair of] contraries themselves, he were to ask for a pair such that from them there will be the opposing contradiction.

Obtaining contraries differs from obtaining the starting thing, however, because the error in the second is in relation to the conclusion (for that is what we look to

224. *APr.* 2.15–16.

when we say that someone asks for the starting thing), while in the case of contraries it lies in the premises standing in a certain relation to each other.

8.14
Training and Practice in Dialectical Arguments

For training and practice in arguments of this sort, first, it is necessary to get into the habit of converting arguments; for this way we will be better equipped in relation to what is said, and also we will know by heart many arguments in knowing by heart a few. For converting is doing away with one of the premises granted by taking the reverse of the conclusion together with the remaining premises asked for; for it is necessary, if the conclusion is not so, for some one of the premises to be done away with, if indeed it was necessary, all of them being posited, for the conclusion to be so.

Also, in relation to every posit look both for a dialectical argument that it is so and for one that it is not so, and, when it has been found, look immediately for its resolution; for in this way the result will be that we will at the same time get training both in asking and in answering, and even if we have no one else to argue with, we can argue with ourselves. **163^b1**

Also, select the dialectical arguments concerned with the same posit and set them alongside each other; for it makes one abundantly well equipped against being forced [to a conclusion], and also has much help to offer in relation to refuting, when one is well equipped to argue both that it is so and that it is not so (for the result is that one is put on one's guard against contrary arguments).

Also, in relation to knowledge and philosophical wisdom, being able to get a comprehensive view, or to have gotten a comprehensive view, of the consequences of either hypothesis is no small instrument; for it remains [only] to choose one or the other of them correctly. In relation to this sort of thing, one must be naturally well-disposed. And this is what it is to be naturally well-disposed as regards truth: to be able to correctly choose the true and avoid the false. And this is just what the naturally well-endowed are able to do; for it is by loving and hating in the correct way what is put before them that they judge well what is best.

In relation to the problems that most often fall to one, one must learn arguments by heart, especially about the first posits;[225] for in the case of these, answerers often give up in despair. Further, one must be well equipped with definitions and have both acceptable beliefs and primary [starting-points] ready to hand; for it is through these that deductions come about.

One must also try to get possession of the [headings] into the province of which other arguments most often fall. For just as in geometry it furthers the work to be

225. I.e., the ones that are especially difficult to argue for or against, because they are or seem to be starting-points ($163^b27–28$).

trained in the elements, and in arithmetic to have the multiplication table up to ten at one's fingertips (it makes a great difference to knowing the multiples of the other numbers too), so likewise in arguments does having things at hand about starting-points, and knowing the premises by heart. For just as in mnemonics,[226] the mere mention of their places (*topoi*) immediately makes the things themselves be remembered, so these [headings] will make one more capable at deducing, because one sees these items defined and numbered. And it is a common premise, rather than an argument, that should be committed to memory; for to be well equipped with a starting-point—that is, a hypothesis—is [only] moderately difficult.

Further, get into the habit of making one argument into many,[227] thus concealing [the conclusion] in the greatest possible unclarity. And it would be of this sort if one stands off as far as possible from things akin to those the argument is about. Among arguments, it will be the most universal ones to which this can be done—for example, that there is not one science of several things; for this way it applies to relatives, contraries, and co-ordinates.

The mnemonics of arguments should be made universal, even if the dialectical argument has to do with a particular case; for in this way too it will be possible to make one argument into many. (It is the same way too in rhetoric in the case of enthymemes.[228]) For oneself [as answerer] one must avoid as much as possible leading deductions toward the universal. And one must always look at arguments to see whether they argue dialectically on the basis of large number of cases; for all the ones that are particular also do so universally, and the demonstration of the universal is present in the particular one, because it is not possible to deduce anything without universals.

Training in inductions must be assigned to a young person; training in deductions to an experienced one. And try to get premises from those skilled at deduction; comparisons from those skilled at induction; for it is in this that each has been trained. In general, try to take away from training in dialectic either a deduction about something, a resolution, an objection, or whether someone asked something correctly or incorrectly (whether oneself or someone else), and why it was so in either case. For it is on these that the capacity is based, and training is for the sake of capacity—especially where premises and objections are concerned; for, simply speaking, the person skilled at dialectic is the one skilled at proposing premises and skilled at proposing objections. And proposing premises is making many things into one (for what the argument aims at must, in general, be taken as one thing), while objecting is making one thing into many (for one either divides or does away with, grants or does not grant, the things that are proposed).

226. Some mnemonic devices associated the things to be remembered with places in (e.g.,) a familiar room, so that by recalling the room, one recalled the things. The *topoi* from which the *Topics* takes its name, have a similar function in relation to dialectical arguments.
227. 157ᵃ1–5.
228. *Rh*. 1356ᵃ35–ᵇ10.

One should not argue dialectically with everyone or train with a random person. For with certain people arguments necessarily become bad; for with someone who tries in every way to appear to escape, it is just to try in every way to produce a deduction, but it is not gracious. That is why one should not readily engage with random people. For the necessary result is a worthless argument; for even trained people are incapable of refraining from arguing dialectically in a contentious way.

One must also have ready-made arguments related to the sorts of problems in which, though we are well equipped with very few, those we have will be useful in relation to the greatest number. These are the universal ones and the ones it is very difficult on the basis of things at hand to be well equipped[229] against.

SOPHISTICAL REFUTATIONS*

Sophistici Elenchi

1
Apparent Deductions and Apparent Refutations

Let us now discuss sophistical refutations, that is, arguments that appear to be refutations, but are really fallacies, not [genuine] refutations, beginning in accord with nature from what comes first. 164ª20

That certain arguments are deductions, while others seem to be but are not, is evident. For just as in other cases this comes about because of a certain similarity, so it is likewise too in the case of arguments. For some people too are in good condition, while others [only] appear to be so, like tribesmen choristers puffing themselves up and bulking up, and some people are beautiful because of their beauty, while other appear so, by using cosmetics. And in the case of inanimate things it is likewise; for some of these are truly silver and other gold, while others are not, though they appear to be so to perception—for example, things made of litharge[1] or of lead appear to be silver, and yellow-colored ones appear to be gold. In the same way, one argument is a deduction or a refutation, while another is not, though it appears such due to lack of experience; for those who lack experience look at things from far away. 25 164ᵇ20 25

For a deduction is when certain things are posited, so that, on the basis of them, it is necessary to assert a thing distinct from the ones proposed,[2] while a refutation is a deduction together with the contradiction of the conclusion. Some of them, however, do not produce this effect, though—due to several causes—they seem to. Among these, one topic, which is most naturally well suited for this purpose and most commonly used, is the one through names. For since it is not possible to bring the things at issue themselves into dialectical arguments, but we use names as symbols[3] instead of things, we think that what follows in the case of the names follows in the case of the things at issue as well, just as in the case of pebbles for those doing rational calculations. But the two are not similar; for names are limited as is the number of statements, while things at issue are unlimited in number. It is necessary, then, for the same statement or a single name to signify several things. Just as in the case of calculation those who are not clever at manipulating the pebbles are cheated by those **165ª1** 5 10

* Translated by C. D. C. Reeve. Text: *Aristotelis Topica et Sophistici Elenchi* (Oxford, 1958; rev. 1984), in consultation with P. Hasper, "Aristotle's *Sophistical Refutations*: A Translation," *Logical Analysis and History of Philosophy* 15 (2013): 13–54.

1. Lead monoxide.

2. Secluding διὰ τῶν κειμένων.

3. Reading χρώμεθα συμβόλοις.

with scientific knowledge, so in the same way in arguments too those inexperienced in the capacity of names argue fallaciously both when arguing themselves and when listening to others.[4]

Due to this cause, then, and others to be mentioned later, there exist both deductions and refutations that are apparent but not real. But since for some people it furthers their work to seem to be wise without being wise rather than to be it without seeming so (for sophistry is apparent wisdom, not real wisdom; and a sophist is someone who makes money from apparent but not real wisdom), it is clear that for them it is also necessary to seem to produce the work of a wise person rather than to produce it and not seem to.

To compare point by point: it is the work of the person who knows a given thing not to speak falsely himself about what he knows, and to be capable of exposing the one who does speak falsely. And of these, the first consists in being capable of giving an argument, the second in being capable of obtaining one. It is necessary, then, for those who wish to play the sophist to look for arguments of the kind just mentioned; for it furthers their work; for a capacity of this sort will make one appear to be wise, which is the end that, having the deliberate choice they have,[5] they aim to achieve.

It is clear, then, that there is a kind consisting of arguments of this sort, and it is this sort of capacity that those we call "sophists" aim at. Let us now speak about how many forms of sophistical arguments there are, how many in number the things are from which this capacity is composed, how many parts there are of their study, and about whatever other things contribute to this craft.

2
Didactic, Dialectical, Examinational, and Contentious Arguments

Of arguments in dialectical discussions, there are four kinds: didactic, dialectical, examinational, and contentious. Didactic ones are those that deduce from the starting-
165b1 points proper to a given subject and not from the beliefs of the answerer (for the learner must take things on trust); dialectical ones are those that deduce from acceptable beliefs in a way that reaches a contradiction; examinational ones are those that deduce from things that seem so to the answerer and that it is necessary for the one to know who pretends to possess the relevant science (in what way has been determined elsewhere[6]); contentious ones are those that deduce or appear to deduce from what appear to be acceptable beliefs, but are not.

4. Ignorance of the fact that there is not a one-to-one correspondence between names and things disposes one to think "same name, same thing," and "distinct name, distinct thing," both of which are false. This is like failing to grasp that the relationship of a pebble to the sheep it stands for need not be one-to-one.
5. *Met*. 1004b22–26, *Rh*. 1355b17–18.
6. *Top*. 8.5–11.

Demonstrative arguments have been spoken about in the *Analytics*, and dialectical and examinational ones elsewhere.[7] About competitive and contentious arguments, let us speak now.

3
Aims of Competitors and Rivals

First, then, we must grasp the number of things that competitors and rivals in arguments aim at. These are five in number: refutation, falsehood, unacceptability, solecism, and, fifth, making the interlocutor babble (and this consists in being compelled to say the same thing repeatedly)—or else, not the real thing, but the appearance of each of them. For competitors and rivals most of all deliberately choose to appear to refute; second, to prove the opponent to be saying something false; third, to lead him into something unacceptable; fourth, to make him commit a solecism (and this is to have made the answerer utter a barbarism by means of the argument); and lastly, to make him say the same thing repeatedly.

4
Modes of Refutation Depending on Speech

The modes of refutation are twofold; for one depends on speech, while the other occurs outside speech. The ways of producing an appearance of refutation depending on speech are six in number. They are homonymy, ambiguity, composition, division, accentuation, and style of speech. For this means of persuasion is through induction—when one assumes another argument to the effect that this is the number of ways in which we can fail to indicate the same thing by the same names or statements—as well as through deduction.

Depending on homonymy[8] are arguments of the following sort: That it is those possessing knowledge who learn (*manthanein*), for it is those who know their letters who understand (*manthanein*) what is dictated to them; for here *manthanein* is homonymous between "understanding by using scientific knowledge" and "acquiring scientific knowledge." Or, again, that evils are good; for what there needs must be is a good, and evil is what there needs must be; for "what there needs must be" is equivocal: [it means] "what is necessary," which often applies to evils (for it is necessary for there to be some evil), and "needed," which we say good things are. Further, "the same person is seated and standing, sick and healthy." For it is the very one who stood up that is standing, and the very one who became healthy that is healthy. But it is the

7. Dialectical ones in the *Topics*; examinational ones perhaps in a lost work.
8. Reading παρὰ τὴν ὁμωνυμίαν.

166ª1 seated one who stood up and the sick one who became healthy. For "the sick person does or suffers such-and-such" does not signify one thing, but at one time "that the person who is now sick . . ." and at another "that the person who was previously sick. . . ." But the person who became healthy was both sick and the person who was sick, while the one who is healthy is not sick, though he is the sick person, not sick now, but the one who was so previously.

Depending on ambiguity are arguments of the following sort: "Wishing that I myself the enemy may capture."[9] Also, "Surely if a person knows a thing, knowing belongs there?" For it is possible to signify as the possessor of knowledge in this statement both the knower and the thing known. Also, "Surely, if a person sees something, seeing belongs there?" But he sees a pillar, therefore seeing belongs to the pillar. Also, "Surely, if you insist on something's being, it you insist on being?" But you insist on a stone's being, therefore you insist on being a stone. Also, "Surely, it is possible for speaking to pertain to the silent?"[10] For "speaking pertaining to the silent" is equivocal between a speaker who is being silent and the things spoken about being so.

There are three modes of arguing that depend on homonymy and ambiguity: One is when a statement or a name strictly speaking signifies several things—for example, "eagle" and "dog."[11] Another is when we customarily use them in that way.[12] A third is when the combination signifies several things, but the separate components signify only one. For example, "scientifically knowing letters"; for it may so happen that each of the two—"knowing" and "letters"—signifies one thing, while the two together signify several, either that the letters themselves have scientific knowledge or that something else has it of them. Ambiguity and homonymy, then, are depended on in these ways.

Depending on composition are arguments of the following sort—for example, "a person is capable of walking while sitting, or writing while not writing"; for it does not signify the same thing if one is dividing and says, capable of "walking-while-sitting," as it does if one is combining; and likewise in the other case, if combining one says, "writing-while-not-writing"; for it signifies that he has the capacity to write while he is not writing. On the other hand, if one is not combining, it signifies that he has the capacity, when he is not writing, to write. Also, "Now he can learn his letters, if indeed he has learned the things he scientifically knows."[13] Further, "Someone who can carry only one thing can carry many."[14]

---

9. The ambiguity is syntactical, depending on whether "I myself" is the subject or object of the verb "capture": I wish that I may capture the enemy; I wish that the enemy may capture me.
10. Plato, *Euthydemus* 300b.
11. *Aetos* is an eagle and a sort of fish (*HA* 540ᵇ18); *kuôn* is a dog, a sort of fish, and the Dog Star, Sirius.
12. I.e., they are ambiguous in use, but not strictly, or semantically, so.
13. Reading μανθάνειν . . . ἐμάνθανεν. Plato, *Euthydemus* 277a. If the scope of "now" is both clauses (combination), the thought is that he is learning what he already knows, which is not learning. If the scope is the first clause, the times of learning and knowing can be different (dividing), so that the whole sentence can be true.
14. Many at one time vs. many over many times.

Depending on division: "Five is two and three, that is, even and odd," and "The greater is equal to the less" (for it is so-and-so much and something further besides). For the same statement divided and combined would not always seem to signify the same thing—for example, "I made you a free man slave,"[15] and "Of men one hundred fifty godlike Achilles left alive."[16]

166^{b}1 Depending on accentuation, in dialectical discussions that are not written down, it is not easy to produce an argument, but it is easier in written exchanges and poetry. For example, some people rectify Homer in response to those who refute as absurd his phrase, *to men ou kataputhetai ombrô[i]* ("this is not rotted by the rain"); for they resolve it by a change of accent, saying the ου more sharply. Also, in the passage about Agamemnon's dream, they argue that Zeus did not himself say, *didomen de hoi euchos aresthai* ("we grant him the fulfillment of his prayer") but ordered the dream to grant it.[17] Arguments of this sort, then, depend on accentuation.

Arguments depending on the style of speech come about when what is not the same is communicated in the same way—for example, a masculine by a feminine, a feminine by a masculine, or either of these by a neuter, or again, a quality by a quantity, a quantity by a quality, a doing by a being affected, or a disposition by a doing, and so on for the others that were distinguished previously; for it is possible for something that is not among the doings to signify by its style of speech something that is among the doings.[18] For example, "being healthy (*hugianein*)" is, in its style of speech,[19] said of things in a similar way to "cutting (*temnein*)" or "building (*oikodomein*)"; and yet the former indicates a certain quality and a way of being disposed, the latter a certain doing. And it is the same way in the case of the others.

Refutations depending on speech, then, are based on these topics.

Of fallacies occurring outside speech, on the other hand, there are seven forms: the first depends on the coincident; the second depends on what is said of things unconditionally or instead not unconditionally, but is so in some respect, place, time, or relation; the third depends on ignorance of what a refutation is; the fourth depends on [affirming] the consequent; the fifth depends on assuming what was initially at issue; the sixth depends on positing the non-cause as a cause; the seventh depends on making many questions into one.

15. I made you a free slave (combination); I made you, a free [man], slave (division). Probably a quotation from an unknown comedy.
16. Of men one hundred and fifty he left alive (combination); of men one hundred, fifty he left alive (division).
17. The passage about wood and rain is *Iliad* 23.328, the one about Agamemnon's dream is *Iliad* 2.1–35, but the words quoted are spoken by Poseidon at 21.297. Hippias' identity is uncertain. See *Po*. 1461^{a}22–23.
18. *Top*. 1.9.
19. *Po*. 1456^{b}9.

5
Fallacies Depending on the Coincident

Fallacies depending on the coincident come about when it is claimed that any affection whatever belongs in the same way to the thing at issue and to its coincident. For since many coincidents belong to the same thing, it is not necessary for all these[20] to belong to what is predicated of the thing as belong to the thing they are predicated of. For example, "If Coriscus is other than a human, he is other than himself, for he is a human." Or, "If he is other than Socrates, and Socrates is a human," then, so they say, "the opponent has agreed that Coriscus is other than a human," because it happens coincidentally that the one he said that Coriscus was said to be other than is a human.[21]

Those depending on what is said of things unconditionally, or instead of things in some respect and not strictly, come about when what is said of things partially is taken as if it applied unconditionally[22]—for example, "If what is not is believable, then what is not is"; for "to be something" and "to be" unconditionally are not the same. Or again, "What is, is not" (if it is not one of the things that is—for example, a human being); for it is not the same thing not to be something and not to be unconditionally. But it appears to be so, because of closeness in speech: "to be something" differs little from "to be," and "to not be something" from "to not be."

Similarly, with the dependence on what is so in a certain respect and what is so unconditionally—for example, the Indian, being wholly black, is white in tooth, therefore he is white and not white. Or, if both affections belong in a certain respect, that contraries belong at the same time. In some cases this sort of fallacy is easily seen by everyone—for example, if having obtained that the Ethiopian is black, the questioner were to ask, whether he was white in tooth; and then, if he obtained that he is white in that respect, he were to think that he had dialectically proved that he was black and not black, because he had reached the end of his questioning with a deduction. In other cases, however, the fallacy is often undetected: wherever, when something is said to be so in a certain respect, its being unconditionally so would also seem to follow, and in those where it is not easy to see which of them is to be assigned in a strict way. This sort of thing occurs when opposites belong in a similar way; for then it seems that either both or neither must be granted to be predicated[23] unconditionally—for example, if something is half white or half black, is it white or black?

20. Reading ταῦτα.

21. The claim is not that Coriscus is coincidentally a human: he is intrinsically and essentially a human. Rather the description, "the one he said that Coriscus was said to be other than," happens to pick out a human. If the one in question is a lion, this would not be so.

22. *APo*. 90ᵃ2–5.

23. Reading κατηγορεῖν.

Fallacies depending on the non-determination of what a deduction is, or what a refutation is, instead[24] depend on an omission from the account [of refutation]. For a refutation is a contradiction of one and the same thing, not of the name but of the thing at issue, and not of a synonymous name, but of the same one, following of necessity from the things granted (not counting what was initially at issue), in the same respect, in relation to the same thing, in the same way, and at the same time. (And it is the same way too in the case of stating a falsehood about something.) Some people appear to refute by omitting one of the stated conditions—for example, arguing that the same thing is the double and not the double; for two is the double of one, but not the double of three. Or, if the same thing is the double and not the double of the same thing, but not so in the same respect; for it is double in length but not double in breadth. Or, if it is the double and not the double of the same thing and in the same respect and way, but not at the same time. That is why there is only an apparent refutation. (One might drag one of this sort into the class of those depending on the speech.)

The ones that depend on assuming what was initially at issue come about in the same way, and in the same number of ways, as those that demand what was initially at issue. They appear to refute because of the incapacity to take a comprehensive view of sameness and distinctness.

167b1 A refutation that depends on [affirming] the consequent is due to thinking that the consequence is convertible; for when, if A is so, B is of necessity so, people also think that if B is so, A is also of necessity so. It is from this too that deceptions concerning belief based on perception come about; for people often take bile for honey because honey is followed along by a yellow color. Also, since the ground becomes wet following rain, if it is wet, we assume that it has rained. But this is not necessarily so. In rhetorical arguments, demonstrations in accord with a sign[25] are based on things that follow; for when speakers wish to prove that a person is an adulterer, they take hold of the consequent—that he is well-dressed or that he is seen wandering about at night.[26] But these affections belong to many people of whom the predicate [adulterer] does not belong. It is likewise too in deductive arguments—for example, the argument of Melissus[27] that the universe is unlimited assumes that the universe cannot come to be (for nothing can come to be from what is not) and that everything that has come to be has come from a starting-point; if, then, the universe has not come to be, it has no starting-point,[28] and so is unlimited. But this does not necessarily follow; for even if what has come to be always has a starting-point, it does not also follow that what has a starting-point has come to be—any more than if a feverish person is hot, it is necessary that a hot one has a fever.

24. Reading ἀλλὰ.
25. *APr*. 70a6–24, *Rh*. 1357b1–17.
26. *Rh*. 1401b23–24.
27. 170b21–24, *Ph*. 1.2
28. Reading ἀρχὴν οὐκ ἔχει.

A refutation depending on taking the non-cause as cause comes about when what is not a cause is added as if the refutation's coming about depended on it. This sort of thing happens in deductions leading to an impossibility; for in these it is necessary to do away with one of the things proposed. If, then, what is not a cause is counted among the questions that are necessary for establishing the resulting impossibility, the coming about of the refutation will often seem to depend on it. For example, the following argument that soul and life are not the same: If coming to be is in fact contrary to passing away, to a certain sort of passing away a certain sort of coming to be is contrary; but death is a certain sort of passing away and is contrary to life; so life is a coming to be and to be alive is to be coming to be; but this is impossible; therefore, soul and life are not the same. But the conclusion is not deduced at all; for the impossibility results even if one does not say that life and soul are the same, but only that life is contrary to death, which is a passing away, and that coming to be is contrary to passing away. Arguments of this sort are not unconditionally non-deductive, but in relation to the thing proposed they are non-deductive. And this sort of thing often goes no less unnoticed by the questioners themselves.

Arguments depending on the consequent and the non-cause, then, are of this sort. Those depending on the making of two questions into one come about when the plurality is not noticed and one answer is given as if to one question. In some cases it is easy to see that there are several questions involved and that one must not give one answer—for example, "Is the earth sea, or is the sky?" In other cases, however, it is less easy, and, on the supposition that it is really one, people either concede by not answering what is being asked or appear to be refuted. For example, "Is A a human and is B?"[29] So, were someone to strike this one and that one, he would strike *a* human and not human*s*.

Or, again, the things among which some are good and some bad, are they all good or not good? For whichever the answerer says would seem to produce either refutation or evident falsehood; for to say that something not good is good, or that something good is not good, is false. Sometimes, if certain premises are added, a genuine refutation might come about. For example, if one grants that one thing and several things are alike said to be white, naked, or blind. For if one thing's being blind is its not having sight when it is natural to have it, several things' being blind will also be their not having sight when it is natural to have it. When, then, one has sight while another does not have it, they will either both be able to see or both be blind—which is just impossible.

29. If the answerer says "yes," he is apparently refuted. Why? Because then it would follow that if someone strikes A and B he would strike one human not two humans. Why? The questioner is asking, "Is A = a human X and is B = a human Y?" There is no presupposition that X = Y. A "yes" answer, however, since it presupposes that only one thing is being asked, does presuppose that X = Y, and so that A = B. But that is not what is being presupposed or asked.

6
Fallacies Based on Ignorance of What a Refutation Is

We must either divide apparent deductions and refutations in this way, or drag all of them into the class of those ignorant of refutation, making this a starting-point; for it is possible to resolve all the ways mentioned into that of the definition of refutation.

First, see whether they are non-deductive; for the conclusion must follow from the things proposed, so that to state it is a matter of necessity, and does not merely appear to be so. Next, we must also see if they are in accord with the [other] parts of the definition. For of those lying in the speech, some depend on equivocation—for example, homonymy, [ambiguity in] the statement, uniform style of speech (for we habitually speak of everything as if it signified a this something); but composition, division, and accentuation are due to the statement not being the same or to the name being different. For the name too, like the thing at issue, must be the same, if there is going to be a refutation or a deduction—for example, if the thing at issue is a cape, do not deduce cloak, but cape. For though the latter is also true, it is not deduced, but rather a further question must be asked, to satisfy the one looking for the why, as to whether "cloak" signifies the same thing.

Those depending on the coincident become evident when deduction is defined. For the same definition must also apply to refutation, except for the addition of a contradiction; for a refutation is a deduction of a contradiction. If, then, there is no deduction of what is coincidental, no refutation comes about. For if, when A and B are, C must of necessity be, and C is [coincidentally] white, there is no necessity for it to be white because of the deduction. Nor, if a triangle has angles equal to two right angles, and it is coincidentally a figure, primary thing, or starting-point, is it because **$168^{b}1$** it is a figure, starting-point, or primary thing that it has this affection; for it is not insofar as it is a figure or a primary thing that the demonstration comes about, but insofar as it is a triangle. And similarly in the other cases too.

So, if a refutation is a sort of deduction, one directed at a coincident would not be a refutation. And yet both craftsmen and scientists generally are refuted by non-scientists on the basis of this; for the deductions they produce against those who know are directed at a coincident, while the latter, being incapable of drawing [the relevant] distinctions, either grant when questioned or, though they did not grant, are thought to have granted.

Fallacies depending on what is so in a respect and what is so unconditionally come about because the affirmation and the denial are not of the same thing. For not white in some respect is the denial of white in some respect, and not unconditionally white of unconditionally white. If, then, the questioner takes the concession that something is white in some respect as saying that it is unconditionally so, he does not produce a refutation, but appears to do so because of ignorance of what a refutation is.

The most evident fallacies (*paralogismos*) of all are those already mentioned[30] as depending on the definition of refutation. That is why indeed they are so called; for it is by depending on (*para*) an omission from the account (*logos*) that the appearance [of refutation] comes about. And if we divide fallacies in this way, we must posit as common to all these cases an omission from the account.

Also,[31] those that depend on assuming what was initially at issue and positing the non-cause as cause are made clear by the definition. For the conclusion must result "because of these things being so," which is precisely what does not hold in the case of non-causes. And, again, the conclusion must follow "without counting what was initially at issue," which is precisely what does not hold of those that depend on demanding what was initially at issue.

Those depending on [affirming] the consequent are a part of those that depend on the coincident; for a consequent is a coincident, but differs from a coincident because a coincident can be obtained in the case of one thing only (for example, that the same thing is something yellow and honey, or white and a swan), while the consequent[32] always involves several things; for we claim that things that are the same with respect to one and the same [third] thing are also the same as each other; which is why a refutation depending on [affirming] the consequent comes about. But this claim is not entirely true—for example, where it is with respect to a coincident; for both snow and swan are the same with respect to white.

Or, again, as in the argument of Melissus,[33] the questioner assumes that having come to be and having a starting-point are the same thing, as are becoming equal and taking on the same magnitude. For because what has come to be has a starting-point, he also claims that what has a starting-point has come to be, on the supposition that these two things, what has come to be and what has a limit, are the same thing as having a starting-point. Similarly too, in the case of things that have become equal, he assumes that if things taking on one and the same magnitude are becoming equal, then things that are becoming equal are also taking on one and the same magnitude. So he assumes the consequent. Since, then, the refutation depending on the coincident lies in the ignorance of refutation, it is evident that the one that depends on [affirming] the consequent does so too. But we must look at this issue from another point of view as well.[34]

Fallacies depending on making several questions into one are due to our failure to articulate the account of what a premise is. For a premise is one thing said of one thing; for the same definition applies to one single thing and unconditionally to the thing—for example, to a human and to one single human.[35] And it is the same way

30. 167ᵃ21–35.
31. Reading τε.
32. Reading παρεπόμενον.
33. 167ᵇ12–20.
34. Chapters 24 and 28.
35. *Met.* 1003ᵇ26–29.

in the other cases too. If, then, one premise claims one thing of one thing, a question of this sort will be unconditionally a premise.[36] And since a deduction is based on premises, and a refutation is a deduction, a refutation is also based on premises. If, then, a premise is one thing said of one thing, it is evident that this fallacy too lies in ignorance of what a refutation is; for in it what appears to be a premise is not really a premise. If, then, a person has given an answer as though to one question, there will be a refutation, but if he has not given one, but only appears to have done so, there will be only an apparent refutation.

So all the modes[37] [of refuting] fall into the province of ignorance of what a refutation is: those depending on speech because the contradiction—which is precisely what we saw to be special to refutation—is only apparent, and the others because they depend on the definition of a deduction.

7
Sources of Deception in Fallacies

In fallacies depending on homonymy and [ambiguity in] the statement, the deception comes about due to being incapable of distinguishing the many ways in which they are said (for in some cases distinguishing them is not puzzle-free—for example, one, being, and same).[38] In those depending on composition and division, on the other hand, the deception is due to thinking that it makes no difference whether the statement is combined or divided, as in most cases. It is similar too in the case of those depending on accentuation; for a word or statement pronounced with a lower and with a higher pitch seldom if ever seems to signify something distinct.

In those depending on the style, the deception is due to similarity in speech. For it is difficult to distinguish what sorts are said of things in one way, what sorts in another way (for the one capable of doing this is pretty much next door to seeing the truth, and it is he most of all who knows when to join in conceding them), because we take everything predicated of a thing to be a this something, and [so] we make our concession as if to one thing; for it is to what is one and a substance that this something and being seem most of all to pertain. This is also why this mode [of refuting] must be put among those depending on speech: first, because the deception occurs more when we are investigating with others than by ourselves (for an investigation with another is through words, while one by oneself is no less through the thing at issue itself[39]); next, because even by oneself one happens to be deceived when one makes one's investigation on the basis of words; still, the deception originates in similarity, and the similarity in speech. **169b1**

36. *Top*. 101b28–33.
37. Reading τρόποι.
38. *Met*. 5, 6, 7, and 9.
39. *Int*. 16a3–8.

In fallacies depending on the coincident, the deception comes about because of not being able to judge same and distinct, one and many, and what sorts of predicates have all the same affections as the thing at issue. It is the same way too in those that depend on [affirming] the consequent; for the consequent is a particular case of the coincident. Further, in many instances it appears to be—and is claimed to be—the case that if this cannot be separated from that, then that cannot be separated from this either.

In fallacies depending on an omission from the account [of what a refutation is] and those depending on what is so in a respect and what is so unconditionally, the deception lies in depending on the smallness of the difference involved; for treating the particular case, the respect, the way, and the time as having no additional signification, we concede universally. It is the same way too in the case of those assuming what was initially at issue, those of the non-cause, and those making many questions into one; for in all these the deception is due to depending on the smallness of the difference involved; for we do not investigate in exact detail either the definition of a premise or that of a deduction due to the cause just stated.[40]

8
Sophistical Refutations

Since we have hold of the number of things apparent deductions depend on, we also have hold of the number sophistical deductions and refutations may depend on. And by a "sophistical refutation" and "sophistical deduction" I mean not only an apparent deduction and refutation that is not really one, but also one that, though real, only appears to be proper to the thing at issue. These are the ones that refute and prove people to be ignorant—which, as we saw,[41] is precisely what it belongs to the examinational craft to do—not in accord with the thing at issue. The examinational craft, though it is a part of dialectic, is capable of deducing a falsehood due to the ignorance of the one conceding the argument. Sophistical refutations, by contrast, even if they deduce the contradictory [of what he proposes], do not make clear whether he is ignorant; for people trip up even those who do know with arguments of this sort.

That we get hold of them by the same methodical inquiry is clear; for the things depending on which it appears to listeners that something has been deduced as a result of questions are the same as those[42] depending on which the answerer would think so too, so that there will be false deductions through all or some of these; for what, without being questioned, one thinks one has granted, one would also grant if questioned. Except, of course, in those cases in which it happens that as soon as the question on the missing point is added, its falsehood becomes evident—for example,

40. 169b10–12.
41. 165b4–6.
42. Reading ταῦτα.

in [fallacies] depending on speech and on solecisms. If, then, fallacious deductions of the contradictory depend on apparent refutation, it is clear that deductions of false conclusions must also depend on the same number of things as an apparent refutation does.

An apparent refutation, however, depends on the parts of a true one; for if a given part is omitted, there would be only an apparent refutation. For example, the one depending on what does not follow because of the argument[43] (the one leading to impossibility); also, the one making two questions into one,[44] depending on the premise; also, instead of the intrinsic, depending on the coincident, and—which is a part of this one—the one depending on [affirming] the consequent.[45] Further, the one that follows not in the case of the thing at issue,[46] but in that of the word; next, instead of the contradictory being universal[47] (and being so in the same respect, in relation to the same thing, and in the same way), depending on a particular case, or depending on one or other of these things; further, depending on not counting what was initially at issue, the one assuming what was initially at issue.[48] Thus we may have hold of how many things fallacies come about by depending on; for they could not depend on more things, but all will depend on the ones just mentioned.

A sophistical refutation is not unconditionally a refutation, but rather one in relation to someone, and the deduction is the same way. For, if the refutation that depends on a homonym does not obtain that it signifies one thing, and the one depending on a uniform style of speech does not obtain that it signifies a this [something] only, and the others in the same way, they will not be either a refutation or a deduction, either unconditionally or in relation to the answerer. But if they do obtain these things, while they will be a refutation or a deduction in relation to the answerer, they will not be so unconditionally; for they have obtained not that they do signify one thing but that they appear to, and from a particular person.

9
The Nature of Dialectic

Without having a scientific knowledge of all the beings, one must not try to get hold of how many things the refutations of those people who are refuted depend on. This, however, does not belong to any craft;[49] for the sciences are perhaps unlimited in number, so that it is clear that their deductions are as well. Plus there are also true

43. 167^{b}21–36.
44. 169^{a}6–16.
45. 168^{b}27–35.
46. 167^{a}21–35.
47. 167^{a}7–20.
48. 167^{a}36–39.
49. Reading οὐδεμιᾶς.

refutations [as well as false or sophistical ones]; for wherever demonstration is possible, it is also possible to refute a person who posits the contradictory of the truth—for example, if someone posits the commensurability of the diagonal, one could refute him by demonstrating that it is incommensurable. So we would need to be scientific knowers of everything; for some refutations will depend on the starting-points in geometry and their conclusions, others on those in medicine, while others depend on those of the other sciences.

But then false refutations likewise also exist in unlimited numbers;[50] for in accord with each craft there is a false deduction—for example, in accord with geometry a geometrical one, and in accord with medicine, a medical one. And by "in accord with a craft" I mean in accord with its starting-points.

It is clear, then, that we must get hold of the topics, not of all refutations, but of those that depend on dialectic; for these are the ones that are common to every craft and every capacity. And as regards the refutation that is in accord with a particular science, it belongs to the corresponding scientist to get a theoretical grasp on whether it, not being a real one, only appears to be one, and if it is a real one, on why it is so. But to get one on a refutation based on what is common, and that falls under no craft, belongs to dialecticians. For if we have hold of what acceptable deductions about anything whatever are based on, we have hold of what refutations are based on; for a refutation is a deduction of a contradictory, so that [to have hold of] one or two deductions of a contradictory is [to have hold of] a refutation.

We have hold, therefore, of the number of things all refutations of this sort depend on. And if we have hold of this, we also have hold of their resolutions; for the objections to these are the resolutions. We also have hold, then, of the number of things that apparent refutations depend on—apparent, that is, not to anyone whatever, but rather to those of the sort mentioned;[51] for if one were to investigate the number of things they depend on to appear so to random people,[52] it would go on indefinitely. So it is evident that to the dialectician it belongs to be capable of getting hold of the things that a refutation, or apparent refutation, that comes about through what is common depends on, that is, a dialectical one or an apparently dialectical or examinational one.

10
Arguments against the Name versus against the Thought

The difference among arguments that some people[53] state when they say that some arguments are directed against the name, others against the thought, does not exist; for it is absurd to suppose that some arguments are directed against the name, others

50. Reading ὁμοίως ἐν ἀπείροις.
51. I.e., dialectically competent ones.
52. *EE* 1214b29–1215a2.
53. Speusippus F69a–b Tarán.

against the thought, rather than the same ones. For what is it not to be directed against the thought except what happens when the questioner does not use the name to apply to what the person being questioned was thinking of when he conceded? And this is the same as to be directed against the name; while it is directed against the thought when the name is used to apply to what the person being questioned was thinking of.

If, then, when a name signifies several things, some people—both the questioner and the one being questioned—were to think that it signifies one thing (for example, "being" and "one" presumably signify several things, but the answerer as well as the questioner in asking his questions are thinking they signify one thing, and the argument is that all things are one), will it have been dialectically argued against the name or against the thought of the one questioned? But, if indeed someone thinks that it signifies several things, it is clear that it is not against the thought. For, first, [the distinction between] being directed against the name and against the thought concerns the sorts of arguments that signify several things, and, next, concerns any argument whatever; for its being directed against the thought does not lie in the argument, but rather in the answerer's being disposed in a certain way toward what has been granted. Next, it is possible for all arguments to be directed against the name; for, on the view under discussion, to be directed against the name is not to be directed against the thought. For if not all admit either of being directed against the name or against the thought, there will be another lot that is neither directed against the name nor against the thought. But these thinkers say all admit of it—that is, that all are divided either into those directed against the name or those directed against the thought, and there are no others.

But then again, among those deductions depending on what is [said in] many ways, [only] some depend on the name. For it is also absurd for them to say that "depending on the name" describes all arguments that depend on speech; on the contrary, there are some arguments that are fallacious not because of the answerer's being disposed in a certain way toward them, but because the argument itself involves asking the sort of question that signifies more than one thing.

Also, it is wholly absurd to discuss refutation without previously discussing deduction; for a refutation is a deduction, so that we must also discuss deduction before false refutation; for a refutation of this sort is an apparent deduction of a contradiction. That is why, if there is an apparent refutation, the cause [of its falsity] will lie either in the deduction or in the contradiction (for the contradiction must be added), but sometimes in both. In the case of "speaking pertaining to the silent," it lies in the contradiction,[54] not in the deduction; in that of "giving away what one

54. "Can speaking pertain to the silent?" "No." "Can speaking pertain to a stone?" "Yes." (Implicit) "Is a stone silent?" "Yes." "Then, speaking can pertain to the silent." This deduction is unproblematic, since there is a univocal interpretation of its premises and conclusion under which it is sound. But there is a problem with the conclusion, since it is ambiguous between a speaker who is being silent and the thing spoken about being so.

does not have," it lies in both;[55] in that of "Homer's poetry being a figure because of being a cycle,"[56] it lies in the deduction. An argument that errs in neither respect is a true deduction.

To return to the point from which the argument digressed: Are arguments in mathematics directed against the thought or not? If someone believes that "triangle" signifies many things, and has granted what he granted not on the supposition that this is the figure about which the questioner has deduced the conclusion that it contains two right angles, has the questioner argued dialectically against the answerer's thought or not?[57]

Further, if the name signifies several things, but the answerer does not understand or think it to do so, how has the questioner not argued dialectically against the thought? Or how else must the question be asked except by conceding a distinction? Suppose then[58] someone asks, "Is it or is it not possible for speaking to pertain to the silent, or is the answer in one way no and in another way yes?" Then, if the answerer does not grant anything, and the questioner continues to argue dialectically, has he not argued dialectically against the thought? And yet the argument seems to be one of those depending on the name. Therefore, there is not any kind of argument directed against the thought.[59] But there are those directed against the name. And yet these do not include all refutations, not only not all real refutations but not even all apparent refutations. For there are also apparent refutations that do not depend on speech—for example, those depending on the coincident and others.

But if someone requires distinctions to be drawn, [for example,] that "By 'speaking pertaining to the silent' I mean sometimes one thing and sometimes another," the

55. "Can someone give what he does not have?" "No." "Can someone give with pleasure what he does not have with pleasure?" "Yes." "Then, someone can give what he does not have." Here the problem is in the deduction and in the contradiction because the initial question is ambiguous between having unconditionally and having in a way, and no univocal interpretation makes the deduction valid.

56. Reading κύκλου. "Is a cycle (circle) a figure?" "Yes." "Is Homer's poetry a cycle?" "Yes." "Then, Homer's poetry is a figure." The problem is in the deduction because it treats the "is" of predication as being the "is" of identity. See *APo*. 77ᵇ31–33.

57. The answerer grants (1) that triangle$_x$ has three interior angles. The questioner soundly deduces the conclusion that (2) the angles of a triangle equal two right angles. The answerer objects (3) that when he granted (1) he took it to be about triangle$_x$, not about triangle. However, the answerer's view that "triangle" signifies many things is false, since "triangle" is in fact univocal. So mathematically speaking, questioner has established (2). The question is, has he established it dialectically? The answer is not so clear.

58. Reading εἶτα.

59. Suppose N is a name said of things in ways W_1 and W_2. Is such-and-such N or not? is an ambiguous question. But it can be transformed into a non-ambiguous one by addition: Is such-and-such N or not, or is it N in W_1 and not N in W_2 or vice versa? If it is not now directed against the thought, then no argument will be. Why? Because the basis for thinking it was directed against the name has been removed. We will be left, then, contrary to the view under discussion, only with arguments directed against the name.

requirement is in the first place absurd; for sometimes the question does not seem to involve [something said in] many ways, and it is impossible to draw a distinction one does not think exists. Next, what else will teaching be but this? For it will make evident how things stand to one who has neither investigated nor knows nor supposes that the thing is said in another way; since what is to prevent this from also being done in cases that do not[60] involve an equivocal signification? "Are the units present in four equal to those present in two? But some twos[61] are present in one way, others in another way." Also, "Is the science of contraries one or not? But some contraries are known, others are not." So a person who makes this demand seems to be ignorant of the fact that teaching is distinct from arguing dialectically, and that a person who is teaching must not ask questions but himself make things clear, while the second must ask questions. **$171^{b}1$**

11
The Examinational Craft

Further, to require an answerer either to affirm or deny is the business not of the person who is proving something but of the one conducting an examination; for the examinational craft is a sort of dialectic and has in view not the person who knows, but the one who is ignorant and pretends to know. The one who gets a theoretical grasp on what is common,[62] as it applies to the thing at issue, is a dialectician, while the one who apparently does so is a sophist. Also, there is a contentious and a sophistical deduction: in the first instance, this is [only] apparently deductive about the things that dialectic is examinational about, even if the conclusion is true (for it is deceptive about the why); and there are those fallacies that are not in accord with the methodical inquiry concerning each of the things, yet seem to be in accord with the craft. For falsely drawn diagrams[63] are not contentious arguments (for the fallacies are in accord with what falls under the craft), certainly not if what the falsely drawn figure concerns is true—for example, the one of Hippocrates, that is, the squaring of the circles by means of lunes. Bryson's way of squaring the circle, on the other hand, even if the circle is squared, is nonetheless sophistical, because it is not in accord

60. Reading μὴ.
61. Reading δυάδες.
62. $170^{a}35–36$.
63. These are falsely drawn in the following sense: they include irrelevant elements on which the deduction actually depends (*Top*. $167^{a}1–3$), so that it is the person who knows that it depends on these who knows how to resolve them ($165^{b}35–36$). But while these elements themselves are neither true nor primary starting-points of geometry ($101^{a}9–10$), the *apparent* deduction embodied in the falsely drawn diagram *is* based on the starting-points and conclusions of geometry (*SE* $172^{a}1–2$, *Ph*. $185^{a}15$), which is why it can deceive even a geometer (*Top*. $132^{a}32–33$), but the actual deduction, which includes the irrelevant elements, is of broader application, because those elements are (*SE* $172^{a}5–6$).

with the thing at issue. So, then, any apparent deduction concerning these things is a contentious argument, and any deduction that appears to be in accord with the thing at issue, even if it is a deduction, is a contentious argument; for it only appears to be in accord with the thing at issue, and so is deceptive and unjust.

For just as injustice in a competition is of a certain form and is a sort of unjust fighting, so in arguing against another, contentious argument is unjust fighting; for in the former case those who deliberately choose to win in any way use all the means, and in the latter case so do contentious arguers. Those, then, who do this for the sake of victory itself seem to be contentious and disputatious human beings, while those who do it for the sake of reputation, with a view to making money, are sophists; for sophistry, as we said,[64] is a sort of craft of making money from apparent wisdom. That is why they seek apparent demonstration, and why, while the arguments of disputatious people and sophists are the same,[65] they are not for the sake of the same things; and the same argument is both sophistical and contentious, though not in the same respect, but rather insofar as it is for apparent victory,[66] it is contentious, while insofar as it is for apparent wisdom, it is sophistical; for in fact sophistry is a sort of appearance of wisdom without the reality.

A contentious arguer stands in something of the same relation to a dialectician as a drawer of false diagrams does to a geometer; for it is on the basis of the same things as those used by dialectic[67] that a drawer of false diagrams leads the geometer[68] to fallacious reasoning. But a drawer of false diagrams is not a contentious arguer, because he draws his false diagrams on the basis of the starting-points and conclusions that fall under the craft [of geometry]. It is clear that the one arguing about the others on the basis of those that fall under dialectic is a contentious arguer. For example, the squaring of the circle by means of lunes is not contentious, while Bryson's way is contentious; and while it is impossible to transfer the former to other subjects (on the contrary, it is directed against geometry only, because it is based on starting-points that are special to it), the former is directed against many people, namely, the ones who do not know what is possible and what is impossible in a given case; for the argument will apply [to many things].[69] Or there is the way Antiphon squared the circle.[70] Or, again, if someone were to deny that it is better to take a walk after dinner because of Zeno's argument,[71] it would not be doing medicine; for it is common. If, then, a contentious arguer stood in every respect in the same relation to a dialectician

70. I.e., by assuming that a circle was a polygon with a large but finite number of sides.
71. *Top*. 160ᵇ8–10.

as a drawer of false diagrams does to a geometer, a contentious argument concerning those things would never have existed.

As things stand, dialectical argument is not concerned with a definite kind, nor is it probative of anything, nor is it even of the same sort as the universal one. For all the beings are not in one kind either, nor, if they were, would it be possible for them to fall under the same starting-points. So none of the crafts proving a certain nature[72] is interrogative; for it is not possible to grant whichever of the two parts [one happens to choose]; for a deduction does not come about on the basis of both. But dialectic is interrogative, while if it proved anything, it would not ask questions, if not about everything, at any rate, not about the primary things and the starting-points proper [to a given science]; for if an answerer does not grant these, one would not have anything further on the basis of which one will further argue dialectically against an objection.

And the same craft is also examinational; for the examinational craft is not of the same sort as geometry either, but is rather one that someone could possess even without having knowledge. For even someone who does not know the thing at issue can undertake an examination of someone who also does not know it, if indeed the latter makes concessions based not on what he knows nor based on things special [to the subject matter of the relevant craft], but on their consequences—that is, on whichever things are of the sort that someone can know without knowing the craft in question, but which if he does not know, he is necessarily ignorant of the craft.

So it is evident that the examinational craft is not the scientific knowledge of anything definite. That is why it is also concerned with everything; for all the crafts also make use of certain common things. That is why everyone, even private individuals, makes a certain use of dialectic and the examinational craft; for everyone tries, up to a certain point, to test those who profess knowledge. And these are the common things; for they themselves know these no less [than the others do], even if they seem to speak from very far outside [the relevant sort of knowledge]. All, then, practice refutation; for they share in an un-craftlike way in what dialectic does in a craftlike one, and the one who by means of the craft of deduction is examinational is a dialectician.

Since there are many of these [common things] and[73] they apply with respect to everything, and are not such as to constitute a certain nature and kind, but instead are like negations, while others are not of this sort but special, it is possible, on the basis of them, to undertake an examination about anything, and for this to constitute a certain craft, though one that is not like the sorts that prove things. That is precisely why a contentious arguer does not in all respects stand in the same position as a drawer of false diagrams; for a contentious arguer will not argue fallaciously on the basis of the starting-points of a definite kind, but about every kind. **172b1**

72. 172a37–38.
73. Reading ταῦτα καὶ.

These, then, are the modes of sophistical refutation. And that it belongs to the dialectician to get a theoretical grasp on them, and to be capable where these are concerned, is not difficult to see; for the methodical inquiry concerned with premises includes this entire theoretical investigation.

12
False and Unacceptable Things

And so about apparent [or sophistical] refutations, we have now spoken. As for proving the opponent to be saying something false and leading the argument into something unacceptable (for this was second in the deliberate choice of the sophist[74]), in the first place this most of all results from getting answers in a certain way and through the questioning. For asking questions directed against[75] no definite proposal is useful in hunting things of this sort;[76] for people are more likely to commit errors when they speak at random, and they speak at random when they have nothing that has been proposed to them. Also, asking several questions, even if what one is dialectically arguing against is something definite, and demanding that the answerer say what he believes,[77] makes one well equipped to lead the answerer[78] into something unacceptable or false, and, if he affirms or denies one of these when questioned, to lead him into things that one is well equipped to attack. Nowadays, though, questioners are less able to do mischief by these means than they were previously;[79] for people demand to know what this has to do with what was initially at issue. An element [or topic] indeed for eliciting a falsehood or something unacceptable is not to ask for any posit directly, but to say that one put questions wishing to learn; for this way of investigating leaves room for an attack.[80]

For proving the opponent to be saying something false, a topic special to sophistry is to lead the answerer into the sorts of things one is well equipped with arguments against. But it is possible to do this both correctly and incorrectly, as was said previously.[81]

Again, for [getting people] to say unacceptable things, look to see what group the one arguing dialectically belongs to, and then question him on something this group says that to most people is unacceptable; for in the case of each school there is something of this sort. An element (or topic) in these cases is having the theses of each group among the premises one has hold of. The fitting resolution to these too is

81. The reference seems to be to *Top*. 2.5.

to bring to light[82] the fact that the unacceptable thing does not result because of the argument, which is what the opponent always really wishes.

Further, [argue] on the basis of things wished for and on professed beliefs; for people do not wish for the same things they say they do, but say the words that make them look best, while they wish for the things that appear most profitable.[83] For example, they say that one should die nobly rather than live pleasantly, and live in just poverty rather than in shameful wealth; but they wish for the contraries. A person, **173^{a}1** then, who speaks in accord with his wishes must be led to state his professed beliefs, while one who speaks in accord with those must be led to state his secret ones; for in either case it is necessary to speak in an unacceptable way; for they will speak contrary either to professed beliefs or to non-professed ones.

But to make people say unacceptable things, the most efficacious topic, as Callicles is represented as stating in the *Gorgias*,[84] and which all the ancients thought conclusive, is the one that depends on what is in accord with nature and what is in accord with convention; for nature (they said[85]) and convention are contraries, and justice is a noble thing according to convention, but according to nature it is not noble. Against a person who speaks in accord with nature, then, one must (they said) respond in accord with convention, while against one who does so in accord with convention one must lead [the argument] to nature; for in both ways it is possible to say[86] unacceptable things. In the view of the ancients, what is in accord with nature was the truth, while what is in accord with convention was what seemed so to many. So it was clear that they too, like those nowadays, tried to refute the answerer, or make him say unacceptable things.

Some questions are such that the answer is unacceptable either way—for example, whether one should obey the wise or one's father, whether one should do what is advantageous or what is just, or whether it is more choiceworthy to suffer injustice or to do harm. One must lead the argument into what is contrary to the views of ordinary people or[87] to the wise—if someone speaks like those who have to do with arguments, into those of ordinary people, if like ordinary people, into those involved in argument.[88] For the latter say that the happy person is of necessity just, while it is unacceptable to ordinary people that a king not be happy.[89] Leading an argument in this way into things that are unacceptable is the same as leading them into the contrariety between what is in accord with nature and what is in accord with convention; for convention is the belief of ordinary people, while the wise speak in accord with nature and truth.

13
Babbling

Unacceptable things, then, must be looked for on the basis of these topics. As for making people babble, we have already said[90] what we mean by "babbling." All arguments of the following sort wish to do this. If it makes no difference whether one says a name or a statement, and double and double of half are the same thing, then if double is double of half,[91] it will be double of half of half. And if "double of half" is again put in place of "double," the expression will be used three times, "double of half of half of half." Also, is appetite for something pleasant?[92] But appetite is desire for something pleasant. Therefore, appetite is desire for something pleasant for something pleasant.

173b1 All arguments of this sort lie in relatives, where not only the kinds but also the things themselves are said in relation to something, and in relation to one and the same thing (for example, desire is desire for something, appetite is appetite for something, and double is double of something: double of half); also where, though the things themselves are not relatives at all, yet the substance, what they are states, affections, or the like of, is indicated in their accounts, since they are predicated of[93] these things. For example, the odd is having-a-middle-number. But there is an odd number; therefore, there is a having-a-middle-number number. And if the snub is concavity in a nose, and there is a snub nose, then there is a concave nose nose.[94]

Questioners sometimes appear to produce babbling, while not really doing so, because they do not get a further answer[95] as to whether "double," said by itself, signifies something or not, and, if it does signify something, whether it signifies the same thing or a distinct one, but instead they state the conclusion straightaway. But because the name is the same, it also appears to signify the same thing.

14
Solecisms

What sort of thing a solecism is has already been stated.[96] It is possible to commit one, to appear to do so without doing so, and to commit one without seeming to, just as Protagoras used to say happened, if *mênis* ("anger") and *pêlêx* ("helmet") are

90. 165b15–17.

95. 181b25–182a6.
96. 165b20–21.

masculine. For a person who says [*mênin*] *oulomenên*[97] ["destroying anger": feminine] commits a solecism, according to him, though he does not appear to others to do so, while one who says [*mênin*] *oulomenon* [masculine] appears to do so, but does not. It is clear, then, that someone could also produce this effect by craft. That is why many arguments appear to deduce a solecism, when they do not really do so, just as in the case of refutations.

Pretty much all apparent solecisms depend on *tode* ("this"), that is,[98] when the inflection indicates neither a masculine nor a feminine but a neuter. For *houtos* ("he") signifies a masculine, *hautê* ("she") a feminine, while *touto* ("it"), though supposed to signify a neuter, often signifies either a masculine or a feminine. For example, "What is it (*touto*)?" "Calliope" [feminine], "A log" [neuter], or "Coriscus" [masculine].

In the masculine and feminine the inflections are all different, while in the neuter some are and some are not. Often, then, when *tode* ("this")[99] has been granted, people deduce as if *touton* ("him") had been said, and likewise substitute one inflection for another. The fallacy comes about because *touto* is common to several inflections; for it signifies sometimes *houtos* ("he" [nominative masculine]) and sometimes *touton* ("him" [accusative masculine]). And it should signify them alternately: when combined with *esti* ("is") it should be *houtos*, while with *einai* ("be" [infinitive]), it should be *touton*—for example, *esti Koriskos* ("it is Coriscus" [nominative]) and *einai Koriskon* ("to be Coriscus" [accusative]). And in the case of feminine nouns it should be the same way, and in that of what are called "object words" that have masculine or feminine designations. For only those that end in *–on* have the [neuter] designation that belongs to objects—for example, *xulon* ("log"), *schoinion* ("rope"). Those that are not like that are masculine or feminine, and some of these we apply to objects—for example, *askos* ("wine-skin") is a masculine noun and *klinê* ("couch") a feminine one. That is why indeed in cases of this sort one with *esti* and one with *einai* will differ in parallel ways.

Also, solecism resembles in a certain way those refutations that are said to depend on similar names for dissimilar things. For just as there we meet solecism in the case of the things at issue, so here we meet it in the case of names; for human and white are both names and things.[100]

It is evident, then, that we must try to deduce a solecism on the basis of the inflections just mentioned.

These, then, are the forms of competitive arguments and the parts of their kinds, and the ways of employing them are the ones mentioned. But it makes no small difference whether the things having to do with the questioning are arranged in a certain way with a view to concealment, just as in the case of dialectical ones.[101] Next in order, then, after what has been said, first this must be discussed.

15
How to Question Effectively

With a view to refutation, one thing is length; for it is difficult to take a comprehensive view of many things at the same time. And to produce length the elements [or topics] that have been mentioned[102] must be used. One is speed; for when people are left behind, they see less far ahead. Further, there is anger and rivalry; for when people are agitated, they are all less capable of being on their guard. Elements [or topics] for [provoking] anger are those making it evident that one wishes to act unjustly and be altogether shameless. Further, putting one's questions alternately, whether one has several arguments related to the same point or arguments that something is so and that it is not so; for the result is that the answerer is made to be on his guard either against several or against contrary arguments at the same time.

In general, all the things useful for concealment that were mentioned before are also useful against competitive arguments; for concealment is for the sake of escaping detection, and escaping detection for the sake of deception.

Against those who refuse anything they think to be in favor of the argument, one must put the question negatively, as if wishing for the contrary of what one wishes, or, at any rate, putting the question impartially; for people haggle less when it is not clear what one wishes to obtain.

Also, in the case of particulars, when someone grants a particular one, often one must not, having done the induction,[103] make the universal the subject of one's question, but rather use it as if it has been granted; for sometimes people themselves even think[104] that they have granted it, and appear to their listeners to have done so, because they remember the induction, and suppose that the questions would not have been asked pointlessly. And in those cases[105] in which the universal is signified not by a name but by a similarity [between the particulars], one must use that to one's advantage; for a similarity often goes unnoticed.

Also, to obtain a premise, one must get contrary answers side by side. For example, if one wishes to obtain that one should obey one's father in everything, one must ask, "Should one obey one's parents in everything, or disobey them in everything?" And ask, "Must one concede that many times many is many or few?" For then, if he had to choose, he would more believe it to be many: for the putting of contraries side by side makes them appear smaller or larger, worse or better, to people.

But often the most blatant of sophistical quibbles on the part of questioners produces an intense impression of refutation, when, not having deduced anything, they

102. *Top*. 157a1–5.
103. Reading ἐπαγαγόντα.
104. Reading οἴονται καὶ αὐτοὶ.
105. *Top*. 157a21–33.

do not make the last thing a question, but state it as a conclusion, as if they had deduced it: "Therefore, so-and-so is not the case."

It is also sophistical, when what is proposed is unacceptable, to demand to be answered with what appears to be so, having initially proposed what seems to be so, putting questions in some such way as this: "Does it seem to you to be so that . . . ?" For if the question is one of the things from which the deduction proceeds, either a refutation or something unacceptable must come about: if he grants it, it will be a refutation; if he does not grant it, and even denies that it seems to be so, it will be unacceptable; and if he does not grant it, but agrees that it seems to be so, it will be refutation-like.

Further, as in rhetorical arguments,[106] so in the same way in refutatory ones one must look for things that are contrary either to the things the answerer says himself or to those that he agrees speak or act well, further, to those that seem to be of this sort or to those similar to them, whether to most people or to all.

Also, just as answerers, at any rate,[107] when they are being refuted, produce an equivocation if their refutation is going to come about, so questioners too must sometimes make use of this against objectors: taken in this way it follows, but taken in that one it does not—and the answerer has assumed it in the latter—as Cleophon does in the *Mandrobulus*.[108]

Questioners who have been hindered in the argument must cut off the rest of their attacks, while an answerer, if he perceives this beforehand, must put in his objection before it happens and forestall it.[109]

And one must sometimes make one's attack against things other than the stated one, having taken the latter in that sense, if one does not have an attack against the one proposed, just as Lycophron did when it was proposed that he deliver an encomium for a lyre.[110]

Against those who demand [an explanation of] what one is making one's attack against (since it seems one must assign the cause, yet some ways of stating it make the defense too easy), one should say (what is the universal result in refutations), "a contradiction" (that is, denying what one has affirmed, and affirming what one has denied[111]), and not that of contraries the science is the same or not the same.

And one must not ask for one's conclusion as a premise, while some premises must not be asked at all, but treated as agreed to.

16
How to Answer Effectively

175ª1 What questions are based on and in what way they must be asked in competitive discussions have now been stated. Next we must speak about answering, about how and what one must provide a resolution of, and for what purpose arguments of this sort are beneficial.

They are useful for philosophy because of two things. For, in the first place, as they depend for the most part on speech, they make us better equipped with regard to how many ways a given thing is said of things, and what sorts of things apply in the same way or in distinct ways both to the things at issue and to their names. Second, they are useful for inquiries of one's own; for a person who easily succumbs to fallacious reasoning due to someone else, and who does not perceive it,[112] will often succumb to it even when it is due to himself. Third, and last, there is a further one relating to reputation: seeming to be trained in everything and not inexperienced in anything; for if someone who is taking part in arguments finds fault with arguments, without having anything determinate to say about their badness, it creates a suspicion that he seems to be making difficulties not due to the truth of the matter but due to inexperience.

How answerers should reply to arguments of this sort is evident, if indeed we have correctly stated previously what fallacies are based on,[113] and those in which the getting of answers has more [of an upper hand][114] have been adequately described. But to take hold of an argument and see and resolve the defect in it is not the same thing as being able to reply to it quickly when one is asked a question; for what we know, we are often ignorant of in a changed context. Further, just as in other areas greater speed or slowness comes about on the basis of training, so it is too in the case of arguments. So, even if something may be clear to us, if we are untrained, we come to it too late for the opportune moment.

And sometimes the same thing happens as with geometrical diagrams;[115] for there, even when we have analyzed, we sometimes cannot reconstruct; so too in refutations we know what the connected thing is that the argument depends on, but are puzzled as to how to resolve the argument.

17
Acceptable Resolutions versus True Ones

First, then, just as we say that we must sometimes deliberately choose to deduce acceptably rather than truthfully, so too we must sometimes provide a resolution

112. Reading μὴ αἰσθανόμενος.
113. Chapters 4–12.
114. Chapters 12–15.
115. *NE* 1112ᵇ20–24.

acceptably rather than in accord with the truth. For, in general, we must fight against contentious arguers not as against refuters but as against apparent refuters; for we say that they are not really deducing, so that it is with a view to their not seeming to do so that one must correct them. For if a refutation is a non-homonymous contradiction based on certain things, there should be no need to draw distinctions against ambiguity and homonymy; for they do not produce a deduction. But there is nothing else for the sake of which one must draw a distinction ahead of time except that the conclusion appears refutation-like.

One must, then, beware not of being refuted, but of seeming to be, since the asking of ambiguous questions, ones depending on homonymy, and all other such ways of cheating, obscure even a true refutation and make it unclear who is refuted and who is not. For since it is possible at the end, when the conclusion is reached, to say that the questioner has not denied precisely what one has affirmed, but rather[116] has done so homonymously, even if it mostly happened to refer to the same thing, it is unclear whether one has been refuted; for it is now unclear[117] whether he is speaking the truth. If, on the other hand, one had drawn a distinction and questioned about the homonymous or ambiguous expression, the refutation would not have been unclear. Also, the thing contentious arguers additionally seek, though less so nowadays and more so previously, that the person being questioned must answer either "yes" or "no," would have come about. But nowadays, because those getting answers ask their questions incorrectly, the person being questioned is compelled to add something to his answer, by way of rectifying the defect in the premise; since if adequate distinctions are drawn, the answerer is compelled to say either "yes" or "no."

If someone will suppose that an argument turning on homonymy is a refutation,[118] it will not be possible for the answerer to avoid being refuted in a certain way; for in the case of visible things, it is necessary to deny about the name what one has affirmed, and affirm what one has denied. For the way in which some people produce a rectification is of no benefit. For they say not that Coriscus is musical and unmusical, but that *this* Coriscus is musical and that *this* Coriscus is unmusical. For the account [of] *this* musical (or unmusical) Coriscus will be the same as [of] Coriscus, [giving] precisely what one is affirming as well as denying at the same time. But perhaps it does not signify the same thing (for neither did the name there), so what is the difference? But if in one case he is going to assign the simple expression "Coriscus," and in another he is going to add "a certain" or "this" to it, it is absurd; for the addition belongs no more in one than in another; for it makes no difference to whichever of the two he adds.

Nonetheless, since if one does not draw distinctions in a case of ambiguity it is unclear whether a person has been refuted or not, and since it is allowed in arguments

116. Rejecting the addition of ἢ.
117. *Top*. 160ª23–32.
118. Rejecting the addition of ἔλεγχον.

to draw distinctions in them, it is evident that not to draw these distinctions, but to grant the question unconditionally, is an error, so that even if the person himself does not seem to have been refuted, at any rate, his argument is similar to a refuted one. It often happens, however, that though people see the ambiguity, they hesitate to draw the distinction, because of the great frequency with which people propose things of this sort, in order not to seem to be making difficulties in response to everything. Then, though they would never have thought that the argument would depend on this, they are often confronted with something unacceptable. So, since one is allowed to draw distinctions, one must not hesitate to do so, as was said previously.[119]

If a person had not made two questions into one, a fallacy depending on homonymy or ambiguity would not have come about either, but rather a refutation or not a refutation. For what is the difference between asking whether Callias and Themistocles are musical or whether two distinct people with one name are? For if one name indicates more things than one, one has asked more questions than one. If, then, it is not correct to demand to obtain one simple answer to two questions, it is evident that it is not fitting to give a simple answer to any homonymous question, even if it is true of all the things [asked about], as some people claim it is. For it is no different from asking whether Coriscus and Callias are at home or not at home, when either they are both there or both not there; for in both cases there are several premises involved; for it is not if the answer is true that the question is one question. For it is also possible, when asked countless distinct questions, for it to be true to say simply "yes" or "no." Nonetheless, one must not answer them with one answer; for this does away with dialectical argument. And it is the same way if indeed distinct things have the same name applied to them. If, then, one must not give one answer to two questions, it is evident that in the case of homonymous questions one must not say either "yes" or "no"; for the speaker has not given an answer [if he does], though he has spoken. But among practitioners of dialectic this is what is in a way demanded, because of neglecting to consider the result.

As we said, then, since there are some seeming refutations that are not really such, in the same way there are some seeming resolutions that are not really resolutions. And these, we say, are the very ones we must sometimes propose rather than the true ones in competitive arguments and in replying to equivocation. In the case of things that seem to be so, one must answer, "let it be so"; for then in fact there is the least likelihood that any refutation on a side issue[120] would come about. But if one is compelled to say something unacceptable, in that case especially one must add "it seems";[121] for in this way neither a refutation nor something unacceptable would seem to have come about.

119. *Top*. 160a17–34.
120. *Top*. 112a8.
121. 174b12–18.

Since it is clear how one asks for what was initially at issue,[122] and people think that they must at all costs do away with things that lie close to [the conclusion], and that some things must not be conceded (on the supposition that the questioner is asking for what was initially at issue), so when someone demands something of such a sort as to necessarily follow from the posit, but is either[123] false or unacceptable, we must say the same thing; for the necessary consequences seem to belong to the posit itself.

Further, when the universal has not been obtained by a name but by a comparison, say that the questioner obtained it neither as granted nor as he proposed it; for a refutation often depends on this too.

If one is prevented from using these, one must go for the conclusion's not having been correctly proved, replying in accord with the division already stated.[124]

When names are used in their strict senses, one must answer either simply or by drawing a distinction. It is when we posit things by supplying the sense in thought—for example, when a question is not asked perspicuously but in a docked way—that a refutation comes about that depends on it. For example: "Is whatever is of the Athenians a possession of the Athenians?" "Yes." "And it is the same way in other cases too?" ["Yes."] "Then, is man of the animals?" "Yes." "Therefore, man is a possession of the animals." [But this is an error.] For we say that man is of the animals because he is an animal, just as we say that Lysander is of the Spartans because he is a Spartan. It is clear, then, that where what is proposed is not perspicuous, one must not concede it in a simple way.

When it seems that of two things that are so, if one of the two is so, of necessity the second is so, while if the second is so, the first is not of necessity so, then, when one is asked which of the two is so, one must grant the weaker (for to produce a deduction based on more things is more difficult). But if the questioner tries to prove that one thing has a contrary, while the other does not, if his argument is true, we must say each has a contrary, but that no name is established for the second one.[125]

About some of the things they say, ordinary people would maintain that anyone who did not concede them was speaking falsely, while about others they would not say it, for example, about those where they have no belief either way (for to ordinary people the question of whether the soul of living things can pass away or is immortal is not something that has been determined). In those cases, then, in which it is unclear in which of two ways what is proposed is usually stated, whether in the way maxims are (for people call both true beliefs and general affirmations "maxims") or in the way "the diagonal is incommensurable" is, where there is no belief either way about the truth, one would most of all go unnoticed in changing the names where these are concerned. For because it is unclear on which side the truth lies, one will not

122. *Top*. 162^{b}34–163^{a}13.
123. Reading ἢ.
124. 168^{a}17–169^{a}21.
125. The questioner will then be forced to show that there is no similarity to unify the nameless class, which is very difficult to do. Cf. *Top.* 157^{a}21–33.

seem to be playing the sophist, and because there being no belief either way, one will not seem to be stating a falsehood; for the change will make the argument irrefutable.

Further, whenever one foresees any question, one must formulate one's objection beforehand and state it ahead of time; for in this way one would most hinder the one putting the questions.

18
Correct Resolutions

Since a correct resolution consists in bringing to light a false deduction, showing what sort of question its falsity depends on, and since something is said to be a false deduction in two ways (for it is one either if a falsehood has been deduced or if what is not a deduction appears to be a deduction), there must be both the resolution mentioned just now and also the rectification of the apparent deduction, showing which of the questions its appearing so depends on.[126] So the result is that one resolves arguments that are genuine deductions by doing away with something, while one resolves apparent ones by drawing distinctions.

Again, since some arguments that really deduce have a true conclusion, while others have a false one, it is possible to resolve those that are false with respect to their conclusion in two ways: either by doing away with one of the questions or by proving that the conclusion does not hold in the relevant way. Those, on the other hand, that are false with respect to their premises can be resolved only by doing away with one of the questions; for the conclusion is true.

So those who wish to resolve an argument must in the first place look to see whether it has proceeded deductively or is non-deductive, and next whether the conclusion is true or false, in order to resolve it either by drawing distinctions or by doing away with [one of the questions], that is, doing away with it either in the one way or in the other, as previously stated.[127]

There is the greatest possible difference between resolving an argument when one is being questioned and when not; for in the former case it is difficult to foresee it, while to see it when at one's leisure is easier.

19
Arguments Depending on Homonymy and Ambiguity

Among the refutations that depend on homonymy and ambiguity, some involve a question that signifies several things, while others have a conclusion that is said in many ways—for example, in the case of "speaking pertaining to the

126. Reading παρὰ τί.
127. 176ᵇ36–177ᵃ2.

silent,"[128] the conclusion is equivocal, and in the case of "not scientifically knowing what one scientifically knows,"[129] one of the questions involves an ambiguity. Also, what is equivocal is sometimes so and sometimes not so—or rather, its being equivocal signifies that it is in one sense so and in another sense not so.

When what is said in many ways appears at the end, no refutation comes about, unless the questioner also obtains the contradiction—as, for example, in the case of "seeing pertaining to the blind"; for without the contradiction there was no refutation.[130] When, on the other hand, what is said in many ways is in the questions, it is not necessary to deny the equivocal thing beforehand; for the argument is not directed at it but is due to it.

Initially, then, one must reply both to a name and to a statement that is equivocal[131] in the following way, saying that in one way it is so and in another way it is not so—for example, that[132] "speaking pertaining to the silent" is possible in one way, but in another not, and that "one needs must do the things that needs must be," is so of some things but not so of others; for things are said to "needs must be" in many ways. But if one failed to notice the equivocation, one must rectify it at the end by adding to the questioning: "Is speaking pertaining to the silent possible?" "No, but speaking pertaining to this person when he is silent is." Similarly, when arguments have what is said in many ways in the premises: "Don't people scientifically know what they scientifically know?" "Yes, but not those who know scientifically in the relevant way." For that it is not possible to scientifically know what one scientifically knows, and that it is not for those who scientifically know in the relevant way, are not the same thing.[133] And, in general, even if the questioner deduces in a simple [or non-equivocal] way, one must contend that what he has denied is not the thing he affirmed but its name, so that there is no refutation.

128. 166ᵃ12–14.

129. 177ᵃ26–30.

130. "Is there seeing pertaining to the blind?" "No." "Wasn't Homer blind?" "Yes." "But people could see him, couldn't they?" "Yes." "So there is seeing pertaining to the blind." The conclusion is not a refutation because it is open to the answerer to say that it was not in that sense that he took the first question when he answered "No." To get a refutation the questioner must also get an answer to the question in its second sense, in which it means "Do blind people see?" The contradictory of an ambiguous statement, in other words, is the contradictory of each of its disambiguated versions.

131. Omitting πρὸς.

132. Reading τὸ.

133. We cannot, when asleep, have *active* scientific knowledge of the things we have *potential* scientific knowledge of, but we can have it when awake.

20
Arguments Depending on Composition and Division

It is evident too how fallacies that depend on division and composition must be resolved; for if the statement signifies something distinct when it is divided and when
35 it is combined, one must state the contrary of what leads to the conclusion. And all arguments of the following sort depend on composition and division: "Was what you saw so-and-so being beaten with what he was beaten with?" and "Was what he was being beaten with what you saw him being beaten with?"[134]

This, then, also has something of ambiguous questions, but it depends on com-
177b1 bination. For what depends on division is not equivocal (for the statement is not the same when divided), if indeed ὄρος and ὅρος, when pronounced in accord with the accentuation, did not signify a distinct thing.[135] In writing, indeed, a name
5 is the same when it is written in the same letters and in like manner (and even there people now add distinguishing marks), but spoken names are not thereby the same. So that what depends on division is not equivocal. And it is evident too that not all refutations depend on equivocation, as some people say.

10 It is for the answerer, then, to make the division; for I saw a man "being beaten with my eyes" is not the same as "I saw with my eyes" a man being beaten. Also, there is Euthydemus' argument, "Do you know now in Sicily that there are triremes in Piraeus?"[136] And again, "Can a person who is good be a cobbler who is bad? Then
15 there could be a bad cobbler who is good. So he will be a good bad cobbler." Again, "Are things of which the sciences are excellent, excellent ones to learn? But the science of what is evil is excellent. Therefore, what is evil is an excellent thing to learn. But surely evil is both evil and a thing to learn, so that evil is an evil thing to learn. But the science of evil things is excellent." "Is it true to say now that you were born?

134. Composition: the answer is (e.g.) "Yes. I saw him being beaten with a stick." Division: the answer is "No. I saw him with my eyes being beaten with a stick."

135. Rejecting the addition of ὡς and seclusion of καὶ. Before the introduction of breathing marks the word pronounced ὄρος (*oros*: smooth breathing) was a homograph of the word ὅρος (*horos*: rough breathing). Nonetheless, it did not signify a distinct thing, since in speech it is divided, with *oros* meaning "mountain" and *horos* meaning "defining mark" or "boundary marker," and neither of these is equivocal. See 169a27–29.

136. If the things involved in the Piraeus example are a trireme, the relation of being (located) in, and the Piraeus, the fallacy consists in arguing from knowing the parts to knowing their combination. What this omits—as in the case of knowing the word because of knowing the letters—is the order of the parts. If a person is in the Piraeus, what he knows he knows in the Piraeus. He knows that there is a trireme (somewhere). But we cannot infer that he knows that there is a trireme (located) in the Piraeus, only that he (located) in the Piraeus knows that there is a trireme (somewhere). In our text the argument is as follows: You are in Sicily now, so that what you know you know there now. One thing you know is that triremes are in Piraeus (sometimes). Those are illegitimately combined to yield the false conclusion. See *Rh*. 1401a26–33.

Therefore, you were born now." Or does it signify something distinct when divided? For it is true to say now that you were born, but not that you were born now.

"Can you do what you are capable of doing in the way you are capable of it? But when you are not playing the lyre, you are capable of playing it. Therefore, you can play the lyre while not playing it." But he does not have the capacity for this, "to play the lyre while not playing it," but rather, when he is not doing it, to do it.

But some people also resolve this in another way. For if the answerer has granted that a person can do it in the way he is capable of doing it, they say that it does not follow that he plays the lyre while not playing the lyre; for it has not been granted that he will do it in every way in which he is capable of doing it, and it is not the same thing to do something in some way in which one is capable and in every way in which one is capable. But it is evident that they do not resolve it correctly; for the resolution of arguments that depend on the same thing is the same, while this resolution will not fit all cases asked[137] for in every way, but is against the questioner, not against the argument.[138]

21
Arguments Depending on Accentuation

There are no arguments, either written or oral, that depend on accentuation except for certain ones, few in number, that might be produced—for example, the following argument: "A house is where (*hou*) you lodge, isn't it?" "Yes." "But isn't 'you do not (*ou*) lodge' the negation of 'you lodge'?" "Yes." "But you said that where you lodge is a house. Therefore, a house is a negation." How, then, this is to be resolved is clear. **178ᵃ1** For *ou* does not signify the same thing when pronounced with a more acute and with a more grave accent.[139]

22
Arguments Depending on Things Said in the Same Way That Are Not the Same

It is also clear how one should respond to arguments depending on things said in the same way that are not the same, if indeed we possess the kinds of predication.[140] For one person has granted, when asked, that something signifying a what-it-is does not belong [to a subject], while another has proved that something signifying a relative

137. Reading ἐρωτωμένους.
138. Since the argument could be rephrased so as to avoid this resolution of it.
139. 166ᵇ3–6.
140. I.e., the categories.

or a quality, but which seems to signify a what-it-is because of speech, does belong [to a subject].

For example, in the following argument: "Is it possible to be doing and have done the same thing at the same time?" "No." "But it is surely possible to be seeing and to have seen the same thing at the same time and in the same respect." [Or in this one:] "Is any being done to a doing?" "No." "Aren't 'is cut (*temnetai*),' 'is burned (*kaietai*),' and 'is affected by a perceptual object (*aisthenetai*)' said of things in the same way, and don't they signify a being done to? Again, 'saying (*legein*),' 'running (*trechein*),' and 'seeing (*horan*)' are said of things in a similar way to each other. But surely seeing (*horan*) is being affected by a perceptual object (*aisthanesthai*), so that it is both a being done to and a doing at the same time."

But if, in the first example, having granted that it is not possible to be doing and have done the same thing, a person were to say that it is possible to be seeing a thing and to have seen it, he has not yet been refuted, if he would not say that seeing is a sort of doing, but rather of being done to; for this question is required in addition, though he is supposed by the listener to have granted it when he granted that cutting (*temnein*) is a doing and having cut (*tetmêkenai*) a having done, and so on with others that are said of things in a similar way; for the listener himself adds the rest, on the supposition that it [seeing] is said in a similar way. But it is not said of things in a similar way, though it appears to be, because of speech. And precisely the same thing happens as in cases of homonymy; for in cases of homonymy a person ignorant of arguments thinks that he has denied the thing he stated, not the name. But an additional question still needs to be asked, whether he said the homonym looking to that one thing; for if he has granted things in this way, there will be a refutation.

The following arguments too are similar to the preceding ones: "If what a person has, he later does not have, he has lost it. For a person who has lost only one dice will not have ten dice." Or is it rather that although what a person does not have and had before, he has lost, it is not necessary for him to have lost as much or as many things as he does not have?[141] Having asked, then, about what he has, he draws [a conclusion] about how many he has; for ten is a how many. If,[142] then, he had asked initially whether "someone not having as many things as he had before has lost that many," no one would have granted it, but would have said either "that many" or "some of them."

Also, the argument that one could give what one does not have; for he does not have one dice only. Rather, he has given, not what he has not got, but what he has not got in the way in which he has given it, as the [only] one he has. For "only" does not signify a this [something], a quality, or a quantity, but a certain relation to something else—for example, that it is not along with anything else. It is, then, as if[143] he

141. Reading ὅσον δὲ μὴ ἔχει ἢ ὅσα.
142. Rejecting the seclusion of εἰ.
143. Reading ὥσπερ οὖν.

had asked, "Could a person give what he does not have?" and, receiving the answer "No," were to ask whether a person could give something quickly that he does not have quickly, and, receiving the answer "Yes," were to deduce that he could give what he does not have. And it is evident that it has not been deduced; for to give quickly is not to give a this [something] but to give in a certain way, and a person could give something in a way that he has not got it—for example, having got it with pleasure, he would give it with pain. **178^{b}1**

Similar too are all the arguments of the following sort: "Could a person strike a blow with a hand he does not have?" or "Could someone see with an eye he does not have?" (For he does not have only one.)[144] Some people resolve it by saying that a person who has more than one eye (or whatever it is) also has only one.[145] Others resolve it as they also resolve, "What a person has, he received"; for this person gave only one vote; and "That person," they say, "has only one vote, received from him."[146] Other people do away with the question immediately, saying that one can have what one has not been given—for example, one can have been given sweet wine but, because of its having been destroyed in the process of transfer, have sour wine.

But, as was also said previously,[147] all these offer a resolution not against the argument but against the person [making it]. For if this was a resolution, if anyone granted the opposite [of what he did], it would be impossible to achieve a resolution, just as happens in other cases. For example, if "it is so in one way, but in another it is not" is the resolution, and the answerer granted it as said unconditionally, the conclusion has been reached. But if a conclusion is not reached, this could not be a[148] resolution. And in the cases mentioned, even if everything is granted, we say that no deduction comes about.

Further, the following also belong among arguments of this sort. "If something is written, did someone write it? But it is written now that you are sitting, which is a false statement, though it was true at the time it was written. Therefore, a statement at once false and true was written." [No,] for the truth or falsity of a statement or belief signifies not a this [something], but a quality; for the same account also applies in the case of a belief. Also, "What does a learner learn? Is it what he learns? But someone learns what is slow fast." It is not what he learns that is meant, therefore, but how he learns it. Also, "Does someone tread on what he takes a walk on? But he takes a walk on the whole day." Rather, it is not what he takes a walk on that is meant but when

144. (1) "Could a person see with an eye he does not have?" "No." (2) "Suppose he saw with both eyes. Then is it true that he did not see with the left one only?" "Yes." "And isn't it also true that he did not see with the right one only?" "Yes." (3) "Then, he must have seen with an eye he does not have, since the left and the right are the only eyes he has."

145. I.e., they treat "only" not as a way of having or possessing something but as a thing had, so that each thing had, regardless of how many there are, is an "only one."

146. "Could a person strike a blow with a hand he does not have, or see with an eye he does not have?" "Yes, because what he has, he has received, and he has not received either his hands or his eyes."

147. 177^{b}31–34.

148. Rejecting the addition of ἡ.

he takes a walk; nor when[149] he drinks a cup is the cup what he drinks but what he drinks from. Also, "Is it either by being taught or by discovering that a person knows what he knows? But if of two things he has been taught one and discovered the other, he has neither been taught nor discovered the two together." Rather, "what [he knows]" means "every individual thing," not "everything collectively."

Also, the argument that there is a third man beyond man-itself and the particular man; for "man" and everything common signifies not a this something but rather such-and-such a quality, quantity, relative, or something of this sort. It is the same way too in the case of Coriscus and musical Coriscus and whether they are the same or distinct. For the first signifies a this something, the second a quality, so that it is impossible for the latter to have been set-out. But it is not being set-out that produces the third man[150] but conceding that it is precisely a this something; for it is also not possible for precisely what is a man to be a this something, as Callias is. Nor will it make any difference if someone were to say that it is not precisely what is a this something that is being set-out but a quality; for there will still be a one over many, like man. It is evident, then, that it must not be granted that what is predicated as common to all is a this something, but that it signifies a quality, relative, quantity, or something else of this sort.

23
Arguments Depending on Speech

In general, in arguments depending on speech, the resolution will always be in accord with the opposite of what the argument depends on—for example, if the argument depends on composition, the resolution will be by division, if it depends on division, by composition. Again, if it depends on acute accentuation, grave accentuation will be the resolution, and if it depends on grave accentuation, acute accentuation. If it depends on homonymy, one can resolve it by saying the opposite name—for example, if [the argument] results in your saying that something is animate,[151] having denied that it is so, make clear in what way it is animate, while if one has said that it is inanimate, but it has been deduced that it is animate, say in what way it is inanimate. It is the same way too in the case of ambiguity. And if the argument depends on similarity of speech, the opposite will be the resolution. "Could one give what one does not have?" Surely not what one does not have, but rather in a way in which one does not have it—for example, one dice only.[152] "Does someone scientifically know what he scientifically knows by being taught or by discovery?"[153] [Yes,] but not the

149. Reading οὐδ' ὅταν.
150. F184, 83.34–85.12.
151. Reading ἔμψυχον.
152. 178ᵇ8–10.
153. 178ᵇ34–36.

things he scientifically knows. Also, whether a person treads on what he takes a walk on; [yes], but not the time. It is the same way too in the case of the others.

24
Arguments Depending on the Coincident

As for arguments depending on the coincident, there is one and the same resolution for all of them. For since it is indefinite at which time a predicate should be said of the thing at issue, when it belongs in the case of its coincident, and since on some occasions it seems and is said to belong, while on others it is said not necessarily to do so, one must, then, once the conclusion has been drawn, say against all of them alike that it does not necessarily belong. One must, however, have an example to put forward.

All arguments of the following sort depend on the coincident: "Do you know what I am going to ask you?" "Do you know the one who is approaching?" or "the one who has hidden his face?" "Is the statue a work of yours?" or "Is the dog your father?"[154] "Is the product of two small numbers a small number?" For it is evident in all these cases that it is not necessary for what is true of the coincident to be also true of the thing at issue; for it is only to things that are indistinguishable with respect to their substance and one, it seems, that all the same things belong; while in the case of something good[, for example,] being good and being what I am going to ask you about are not the same. Nor in the case of someone approaching is being the one who is approaching (or the one who has hidden his face) the same as being Coriscus. So, if **179b1** I know Coriscus but do not know the person approaching, I know and do not know the same person. Nor, again, if this is mine and also a work, is it a work of mine. Instead, it may be my possession, or thing, or something else. And it is the same way in the other cases too.

Some people resolve these by doing away[155] with the question. For they say that it is possible to know and not to know the same thing, but not in the same respect. When, then, they do not know the person approaching but do know Coriscus, they say that they do know and do not know the same thing, but not in the same respect. And yet, in the first place, as we have already said,[156] the rectification of arguments depending on the same thing must be the same. But this will not be so if one takes the same claim to apply not to knowing but to being or being in a certain state—for example, in "If this [dog] is a father and this [dog] is yours . . ."; for if this is true

154. Plato, *Euthydemus* 298e.
155. Reading ἀναιροῦντες.
156. 177b31–32.

in certain cases, that is, that it is possible to know and not to know the same thing, even so, what has been said about it has nothing in common with the latter case.[157]—

(There is nothing to prevent the same argument from having several defects, but not every bringing to light of a defect constitutes a resolution; for it is possible for a person to prove that something false has been deduced, but not to have proved what it depends on—for example, in the case of Zeno's argument that movement is impossible. So even if he were to try to infer an impossibility, in leading [the argument] to the impossible, he is making an error,[158] even if he has deduced it innumerable times. For this is not a resolution; for a resolution, as we just saw, is a bringing to light of what the falsehood of a false deduction depends on.)

—If, then, it has not been deduced, or in addition he tries to infer a truth or a falsehood,[159] the making clear of that is a resolution. Perhaps, indeed, there is nothing to prevent this from happening in some cases, albeit in the ones under consideration, at any rate, this would not seem to be so; for one knows both of Coriscus that he is Coriscus and of the thing approaching that it is approaching. But to know and not to know the same thing does seem to be possible—for example, one can know the pale thing and not know the musical one; for in this way one does know and does not know the same thing, but not in the same respect. But, as for the thing approaching and Coriscus, he knows both that it is approaching and that it is Coriscus.[160]

Those who resolve the argument that every number is small also err in a similar way to those we have mentioned; for if, when the conclusion has not been reached, they pass this over and say that the conclusion has been reached and is true (for every number is both large and small), they make an error.

---

157. The resolution or rectification of the argument, (1) "This dog is a father. This dog is yours. Therefore, this dog is your father" ought to be the same as that of (2) "Do you know the one who is approaching?" since they exploit the same thing. But the suggested resolution of (2), that one can know and not know the same thing, but not in the same respect, does not apply to (1). So it is not a genuine resolution of (2).

158. Reading ἐπιχειροίη συνάγειν ὡς ἀδύνατον συνάγων εἰς ἀδύνατον, ἁμαρτάνει. The reference is to someone providing a putative resolution of an argument by producing a *reductio ad absurdum* argument against its conclusion, thereby proving the deduction false. Even if he succeeds, he will not have brought to light what the false deduction is false through, and so will not have provided a resolution of it, and so will have made an error.

159. Removing the obeli on ἢ καὶ ἀληθὲς ἢ ψεῦδος.

160. Rejecting the addition of ὅν. The principle underlying this initially opaque argument is this: "it is only to things that are indistinguishable with respect to their substance and one, it seems, that all the same things belong to" (179ᵃ37–39). So all the same things belong to Coriscus and to Coriscus, since he is indistinguishable from himself in substance or essence. "The thing approaching" is not a classically understood definite description but is functioning in the context as an indexical: *that* thing approaching. So that whatever is true of *it* is true of whatever is indistinguishable from it with respect to its substance or essence. But it is—one and the same thing as—Coriscus, so everything true of it is true of Coriscus and vice versa. But it is true of the thing approaching that one knows it is approaching, so it is true of Coriscus that one knows that he is approaching.

Some people also resolve the deductions by appeal to equivocation—for example, by saying that what is "yours" is a father, son, or slave. And yet it is evident that if the appearance of refutation depends on what is said of things in many ways, the name **180^{a}1**
or the statement must be said literally of several things. No one says that B is literally A's child if A is the child's master; rather, the composition depends on what is coincidental. "Is B yours?" "Yes." "Is B a child?" "Yes." "Then B is your child" (because he 5
is coincidentally both yours and a child). But he is not your child.[161]

There is also the argument that being something of evils is good. "For practical wisdom is scientific knowledge of evils." But being this of these is not said of things in many ways, but is said of a possession. If, however, it is said of things in many ways (for we say that man is of the animals, though not a possession of theirs, and 10
if the relation of so-and-so to evils is said as its being of them, because of this it is a so-and-so of evils; but it is not one of the evils), it appears to depend on what is in a certain respect and unconditionally.

And yet it is perhaps possible for something of evils to be equivocally good, although not in the case of this argument, but rather if one were to say a slave is 15
good of the wretched.[162] But perhaps it is not even this way here; for if something is good and of someone, it is not at the same time good of someone. Nor is the expression "man is of the animals" said in many ways; for if we sometimes signify something elliptically, this is said in many ways; for in fact by quoting the half-line, 20
"Sing, goddess, the wrath,"[163] we signify "recite me the *Iliad*."

25
Arguments Depending on Strict and Unconditional versus in Some Respect

Arguments that depend on what is said to be this in the strict sense, or else in some respect, place, way, or relation to something, and not unconditionally, must be resolved by looking at the conclusion in relation to its contradictory, to see whether it can possibly be qualified in any of these ways. For it is impossible for contraries and 25
opposites, or an affirmative and a negative, to belong unconditionally to the same thing. However, there is nothing to prevent each from belonging in some respect, relation, or way, or one in some respect and the other unconditionally. So, if this one belongs unconditionally and this other one belongs in a certain respect, there is as yet no refutation; and this is something one must look at in the conclusion in relation to its contradictory. 30

161. Reading ὅτι συμβέβηκεν εἶναι καὶ σὸν καὶ τέκνον. ἀλλ' οὐ σὸν τέκνον.
162. As in, "the best of a bad lot."
163. The opening words of Homer's *Iliad*.

All arguments of this sort involve the following: "Is it possible that what is not is? But surely it is, at any rate, something that is not." Similarly, what is will not be; for it will not be one of the beings. "Is it possible for the same person at the same time to be a keeper and a breaker of his oath?" "Is it possible for the same person at the same time to obey and disobey the same order?" Or rather is it not that being something and being unconditionally are not the same (for it is not the case that if what is not is something, it also is unconditionally)?[164] Nor if a person keeps his oath on this or in this respect is he necessarily also [unconditionally] a keeper of oaths (and a person who swears[165] that he will break his oath, has, in breaking it, kept this one only, but is not [unconditionally] a keeper of oaths). Nor does he who disobeys obey
180b1 [unconditionally], but rather he obeys in this.[166]

The argument is similar too about whether it is possible for the same person to lie and at the same time be truthful. But because it is not easy to see whether[167] one should assign the "unconditionally" to "be truthful" or to "lie," it appears difficult [to resolve]. However, there is nothing to prevent the same person[168] from being unconditionally a liar but truthful in a certain respect or in relation to a certain thing, that is, truthful in some things, though not himself truthful.

It is the same way too in cases of being in relation to some thing, place, or time; for all the arguments of this sort depend on the following: "Is health, or wealth, a good? But to a person without practical wisdom who uses it incorrectly, it is not good. Therefore, it is good and not good." "Is being healthy, or having power in the city, good?[169] But sometimes it is not better [than other things]. Therefore, the same thing is good and not good for the same person." Or is there nothing to prevent something from being unconditionally good but not good for a particular person, or good for a particular person, but not good now or not here? "What a practically wise person would not wish for, is it bad? But he does not wish to get rid of the good. Therefore, the good is bad." No, for it is not the same thing to say that the good is bad and that to get rid of the good is bad. And it is the same way too with the argument about the thief; for it is not the case that if a thief is bad, taking is bad too. Therefore, he does not wish for the bad, but the good; for taking a good thing is good.[170] Also, disease is bad, but not to get rid of disease.

164. *Met.* 1030a25–26, *Rh.* 1402a3–7.
165. Reading ὁ δ'.
166. "Is it possible for the same person at the same time to obey and disobey the same order?" "No." "But the order was to disobey the order."
167. Reading ποτέρως.
168. Reading τὸν αὐτὸν.
169. Reading ἀγαθόν.
170. Reading τὸ γὰρ λαβεῖν ἀγαθὸν ἀγαθόν. The argument, since it must be similar to the previous one, is something like this: A thief is bad. Therefore, what he does (namely, taking) is bad. No, because what he wishes for, in taking, is something good, and taking a good thing is good.

"Is what is just more choiceworthy than what is unjust and what is justly done than what is unjustly done? But it is more choiceworthy to be put to death unjustly." "Is it just for each to have his own? But whatever things someone has judged in accord with his own belief, even if false, have the controlling votes in the eyes of the law. Therefore, the same thing is just and not just." Also, "Should judgment be in favor of those who state just things or those who state unjust things? But surely it is just for a person who suffers injustice to state fully the things he has suffered; and these were unjust ones." [These are fallacies.] For if to suffer something unjustly is more choiceworthy, it does not follow that unjustly is more choiceworthy than justly. On the contrary, unconditionally, justly is more choiceworthy, although there is nothing to prevent unjustly from being more so than justly in this case. Also, to have what is one's own is just,[171] while to have what is another's is not just, yet there is nothing to prevent this judgment from being just—for example, when it is in accord with the one who is doing the judging; for if it is just in this case[172] or in this way, it does not follow that it is also unconditionally just. Similarly too when things are unjust, there is nothing to prevent saying them, at any rate, from being just; for if saying them is just, it does not necessarily follow that they are just, any more than if it is beneficial to say things, they are beneficial. And it is the same way in the case of just ones too. So, if the things said are unjust, it does not follow that the person who says unjust things prevails;[173] for he says things that are just to say, but that are unconditionally unjust, that is, unjust to suffer.

26
Arguments Depending on the Definition of a Refutation

Arguments depending on the definition of a refutation must be replied to, as suggested previously,[174] by looking at the conclusion in relation to its contradictory, and seeing in what way it will involve the same thing, in the same respect, in relation to the same thing, in the same way, and at the same time. And if this additional question has been asked initially, one must not agree that it is impossible for the same thing to be double and not double, but state that it is possible, only not in such a way as was agreed to be a refutation. All the following arguments depend on this sort of thing. "Does a person who knows that a given thing is the given thing it is, know the thing? And the same for a person who does not know it? But one who knows that Coriscus is Coriscus might not know that he is musical, so that he both scientifically knows and does not know the same thing." "Is what is four cubits long greater than what is three cubits long? But what is three cubits long might become four cubits long. But

171. *Rh.* 1366^{b}9–11.
172. Reading τοδὶ.
173. Reading νικᾷ.
174. 167^{a}21–27, 180^{a}24–25.

what is greater is greater than the lesser. Therefore, the thing in question is greater and less than itself in the same respect."

27
Arguments Depending on Asking for What Was Initially at Issue

As for arguments that depend on asking for and obtaining what was initially at issue, if this is clear, one must, when asked, not grant it, even if it is acceptable, while stating the truth.[175] If, on the other hand, it is concealed, one must, because of the defectiveness of such arguments, turn the charge of ignorance back on the questioner, saying that he is not arguing dialectically; for a refutation must do without what was initially at issue. Next, one must say that it was granted on the supposition that it would not be used [as a premise], but used to produce a deduction against it, the contrary way to that in the case of refutations on side issues.

28
Arguments Depending on Affirming the Consequent

Also, those arguments that infer by means of [affirming] the consequent must be exposed in the course of the argument itself. For the logical sequence of consequents[176] is twofold; for it is either as the universal follows [in a logical sequence of consequents] the particular, for example, as animal follows from human (for it is claimed that if this accompanies that, that accompanies this), or else in accord with opposition (for [it is claimed that] if this follows that, the opposite of the one follows the opposite of the other). It is on this too that the argument of Melissus[177] depends; for [he claims that] if what has come to be has a starting-point, what has not come to be does not have one, so that if the heaven[178] has not come to be, it is also unlimited. But this is not so; for the logical sequence is the reverse.

29
Arguments Depending on an Addition

One must look at any arguments where the deduction depends on an addition to see whether, when it is subtracted, the impossibility follows nonetheless.[179] And one

175. Reading λέγοντα. I.e., one must state that it begs the question. See 176ᵃ27–31.
176. See *Int.* 19ᵇ19–22, *Top.* 113ᵇ15–26.
177. See 167ᵇ13–20.
178. I.e., the universe. See *Cael.* 278ᵇ11–21.
179. 167ᵇ21–36.

must next bring this to light, and say that one had granted it not as something one believed, but for the purposes of the argument, while the questioner has made no use of it for the purposes of the argument.

30
Arguments Depending on Making Many Questions into One

Against arguments that make many questions into one, one must draw a distinction right at the start; for a question is one to which there is one answer, so that one must not affirm or deny several things of one thing or one thing of several things, but one thing of one thing. But just as in the case of homonyms,[180] where a homonym **181b1** sometimes belongs to both or to neither, so that, though the question is not simple, nothing results to affect those who give a simple answer, so it is too in these cases. When, then, the several predicates belong to one thing, or the one predicate to several things, no contradiction results for those who give a simple answer and have made this error, but rather when something belongs to one and not to another thing, or several things are affirmed of several. And there is a way in which both belong to both, while in another way again they do not, so one must beware of this. For example, in these arguments: "If one thing is good and another is bad, it is true to say that these things are good and bad, and again that they are neither good nor bad (for each of the two is not each of the two), so that the same thing is both good and bad and neither good nor bad." Also, "If each thing is the same as itself and distinct from another thing, since[181] these things are not the same as other things, but as themselves, and also distinct from themselves, the same things are both distinct from themselves and the same as themselves." Further, "If the good becomes bad and the bad good, they would become both." Also,[182] "Of two unequal things, each is equal to itself, so that they themselves are equal and unequal to themselves."

These arguments also fall into the province of other resolutions; for "both" and "all" signify several things;[183] therefore, it does not follow that one has affirmed and denied the same thing, except in name. And this, as we saw,[184] is not a refutation. On the contrary, it is evident that if several things do not give rise[185] to one question, but rather one predicate is affirmed or denied of one thing, there will not be [a deduction of] an impossibility.

31
Arguments Depending on Babbling

Where arguments leading one to say the same thing several times are concerned, it is evident that one must not grant that predicates said as relatives signify something when in separation by themselves—for example, "double" without[186] "double of half," just because it appears in it. For "ten"[187] is also in "ten minus one," "do" in "not do," and, in general, the affirmation in the negation. Nonetheless, if one says, "this is not white," one is not saying that it is white. Perhaps "double" does not signify anything at all, any more than in the case of half.[188] But even if "double" does signify something, it is not the same thing as when it has been brought together [with its correlate]. Nor does "scientific knowledge" in a form of it (for example, if it is "medical scientific knowledge") signify precisely what the common thing is, which, as we saw,[189] is scientific knowledge of the scientifically knowable.

In the case of things that are predicated of the things through which they are indicated, one must say that they are not the same separately as in the account indicating them. For "concave" indicates the same common thing in the case of the snub and the bandy, but when added, in the one case to "nose" and in the other to "leg," there is nothing to prevent it from signifying distinct ones; for in the first case it signifies
182ᵃ1 snub and in the second bandy, and it makes no difference whether one says "snub nose" or "concave nose."

Further, one must not grant the expression in the nominative; for that is false; for the snub is not snub nose [nominative] but something—for example, an affection—characteristic of a nose [genitive], so that there is nothing absurd in supposing that a snub nose is one having the concavity characteristic of a nose.

32
Arguments Depending on Solecisms

Where solecisms are concerned, we said previously what their appearing to follow depends on.[190] How they must be resolved will be evident from the arguments themselves; for all of the following sort wish to establish a solecism: "Is this (*ho*$_{\text{n. nom.}}$) truly what you truly state it (*touto*$_{\text{n. acc}}$) to be? But you say something is a stone (*lithon*$_{\text{m. acc.}}$). Therefore, something is a stone (*lithon*) [nom. is required]." On the contrary, in

186. Reading ἄνευ.
187. Reading τὰ.
188. Reading τὸ ἐν τῷ ἡμίσει.
189. *Cat.* 11ᵃ24–32, *Top.* 108ᵃ9.
190. 173ᵇ17–174ᵃ11. In what follows, genders and cases are indicated by suffixes with the usual abbreviations: m. (masculine), f. (feminine), n. (neuter), nom. (nominative), acc. (accusative), gen. (genitive).

speaking of a "stone", one says not "he (*ho*$_{\text{n. nom.}}$)" but "him (*hon*$_{\text{m. acc.}}$)," and not "this (*touto*$_{\text{n. nom.}}$)" but "this (*touton*$_{\text{m. acc.}}$)." If, then, one were to ask, "Is it this (*touton*) [*houtos*$_{\text{m. nom.}}$ is required] him (*hon*$_{\text{m. acc.}}$) you truly say?" one would not seem to be speaking correct Greek, any more than if one were to ask, "Is it he (*houtos*$_{\text{m. nom.}}$) her (*hên*$_{\text{f. acc.}}$) [m. is required] one says he is?" But to say "wood (*xulon*$_{\text{n. acc.}}$)" for "he," or whatever signifies neither something feminine nor something masculine, makes no difference. That is why no solecism comes about if you say, "Is this (*ho*$_{\text{n. nom.}}$) what you say it (*touto*$_{\text{n. nom.}}$) is? You say it is wood (*xulon*$_{\text{n. acc.}}$). Therefore, it is wood (*xulon*$_{\text{n.}}$)." "Stone," on the other hand, and "he" (*houtos*) have masculine denomination.[191] If, then, one were to ask, "Can he (*houtos*) be a she (*hautê*)?" or, again, "Is he (*houtos*) not Coriscus?" and then were to say, "Therefore, he (*houtos*) is a she (*hautê*)," one has not derived a solecism, not even if "Coriscus" signifies precisely a she (*hautê*), because the answerer does not grant this. Instead, this point must be asked as an additional question. But if this is not the case nor does the answerer grant it, then the solecism has not been deduced either in reality or in relation to the one who was questioned.

Similarly, then, in the first example too "he (*houtos*)" must signify the stone. If, however, this is neither so nor is granted, the conclusion must not be stated, although, by depending on the fact that the dissimilar case of the name appears to be similar, it appears to follow.

"Is it true to say that this (*hautê*$_{\text{f. nom.}}$) is just what you said this (*autên*$_{\text{f. acc.}}$) is? You said it is a shield (*aspida*$_{\text{f. acc.}}$); therefore, it is a shield (*aspida*) [nom. is required]." On the contrary, this is not necessary if "this (*hautê*$_{\text{nom.}}$)" signifies not a shield (*aspida*$_{\text{acc.}}$) but a shield (*aspis*$_{\text{nom.}}$), while "this (*tautên*$_{\text{acc.}}$)" signifies a shield (*aspida*$_{\text{acc.}}$).

Nor is it necessary, if he (*houtos*$_{\text{m. nom.}}$) is who you say he (*touton*$_{\text{m. acc.}}$) is, and you say he is Cleon (*Kleôna*$_{\text{acc.}}$), is he (*houtos*$_{\text{nom.}}$) therefore Cleon (*Kleôna*$_{\text{acc.}}$); for he (*houtos*$_{\text{nom.}}$) is not *Kleôna*$_{\text{acc.}}$ [but rather *Kleôn*$_{\text{nom.}}$]; for what was said was that he (*houtos*$_{\text{nom.}}$), not him (*touton*$_{\text{acc.}}$), is who you say he is; for it would not be correct Greek either if the question had been asked in the latter way ["Is him who you say he is?"].

"Do you scientifically know this (*touto*)? This (*touto*) is a stone (*lithos*$_{\text{nom.}}$). Therefore, you scientifically know a stone (*lithos*$_{\text{nom.}}$) [*lithon*$_{\text{acc.}}$ is required]." On the contrary, "this (*touto*)" does not signify the same thing in "do you scientifically know this (*touto*)?" and in "this (*touto*) is a stone," but rather in the first it signifies this (*touton*$_{\text{acc.}}$), and in the second this (*houtos*$_{\text{nom.}}$).

"When you have scientific knowledge of something (*hou*$_{\text{gen.}}$), do you scientifically know it (*touto*$_{\text{acc.}}$)? But you have scientific knowledge of a stone (*lithou*$_{\text{gen.}}$). Therefore, you scientifically know of a stone (*lithou*$_{\text{gen.}}$)." On the contrary, "of something (*hou*$_{\text{gen.}}$)" says "of a stone (*lithou*$_{\text{gen.}}$)," and "it (*touto*$_{\text{acc.}}$)" says a stone (*lithon*$_{\text{acc.}}$). And it was granted that when you have scientific knowledge of something (*hou*$_{\text{gen.}}$), you

191. Reading κλῆσιν.

182ᵇ1 scientifically know not of it (*toutou*$_{gen.}$) but it (*touto*$_{acc.}$), so that you scientifically know not of a stone (*lithou*$_{gen.}$) but a stone (*lithon*$_{acc.}$).

That arguments of this sort do not deduce a solecism, though they appear to do so, and why they appear to do so, and in what way one must reply to them, is evident from what has been said.

33
Simpleminded versus Incisive Arguments

We must also understand that, among all arguments, it is easier with some, more difficult with others, to see by depending on what, and at what point, they mislead the listener by arguing fallaciously—although the latter are sometimes the same arguments as the former; for one must call an argument "the same" that depends on the same thing. But the same argument might seem to some people to depend on speech, to others on the coincident, and to others on something else, because, when [the words in it are] changed, each is not then equally clear.

Just as in the case of those that depend on homonymy, then, which seems to be the most simpleminded mode among the fallacies, some are clear even to random people. (For pretty much all ridiculous arguments depend on speech. For example, "A man was carried down from a ladder by a chariot."[192] And "Where are you bound? To the yardarm." "Which of two cows will calve in front?[193] Neither; but both will calve in the rear." "Is Boreas pure? Certainly not; for he has killed the drunken beggar."[194] "Is he *Euarchos*? Certainly not. He is *Apollônidês*."[195] And it is the same way with pretty much the vast majority of the rest.) Others, however, apparently escape the notice of even the most experienced. A sign of this is that people often fight about the names, for example, about whether "being" and "one" always signify the same thing, or something distinct; for to some people "being" and "one" seem to signify the same thing in all cases, while others[196] resolve the argument of Zeno and of Parmenides by saying that being and one are said of things in many ways.

Similarly too, where the coincident and each of the others is concerned,[197] some of the arguments will be easier to see, others more difficult, and to grasp which kind they belong to, and whether one is a refutation or not a refutation, is not equally easy for all of them.

192. The double meaning of the sentence is obscure.
193. "In front" temporal vs. "in front" spatial.
194. Pure of guilt vs. pure in the sense of unadulterated or clean. Boreas, the North Wind, was thought to be a "clean" wind.
195. *Euarchos* means "rules (*archein*) well (*eu*)," while *Apollônidês* seems to derive from *apollunai*, which means "to destroy utterly," "kill."
196. Including Aristotle himself. See *Met.* 1018ᵃ35–36.
197. Reading καὶ περὶ τὸ συμβεβηκὸς καὶ περὶ τῶν ἄλλων.

An incisive argument is one that makes one most puzzled; for it bites most deeply. A puzzle is twofold: one occurs in dialectical arguments that are deductive, when one is in doubt as to which of the questions asked one must do away with; the other occurs in contentious arguments,[198] about how one is to state what has been proposed. That is precisely why, among deductive ones, the more incisive arguments make one inquire more.

A deductive argument is most incisive when from the things that seem most of all to be so it does away with the most acceptable belief; for though it is a single argument, it will, when the contradiction is converted,[199] contain deductions that are all similar in character; for it will always, on the basis of acceptable beliefs, do away with one that is equally acceptable, which is precisely why it is necessary to be puzzled.[200] **183^{a}1** This sort of argument, then, is most incisive, namely, one which puts the conclusion on an equal footing with the questions, while the one based on those that are on a similar footing is second; for this will produce similar puzzlement as to which of the questions must be done away with. But this is difficult; for one must do away with something, but what to do away with is unclear.

The most incisive of contentious arguments, on the other hand, is in the first place one where it is not immediately clear whether [the conclusion] has been deduced or not, that is, whether the resolution depends on a falsehood or on drawing a distinction; second among the others is where it is clear that it depends on drawing a distinction or doing away with something, but it is not evident which of the questions it is that, by doing away with it or drawing distinctions in it, one is to resolve it, but [only] whether[201] it depends on the conclusion or on one of the questions.

Sometimes, an argument that does not deduce is simpleminded, if the premises are too unacceptable or false; but sometimes it does not deserve to be despised. For when one of the questions is omitted of the sort that the argument is about and which it is due to, the deduction that has both not obtained this in addition[202] and not deduced [the conclusion] is simpleminded. But when what is omitted is

198. Chapter 17.

199. *APr*. 59^{b}1–5.

200. Start with (A): (1) All mothers love their children (very acceptable belief); (2) Medea was a mother (fact or very acceptable belief); therefore, (3) Medea loved her children (false). Then, taking the contradiction of (3), (3*) Medea did not love her children, construct two other deductions in which it is used in a changed position with each of (1) and (2) to subvert the other, as follows: (B) All mothers love their children; (3*) Medea did not love her children; therefore, Medea was not a mother. (C) (3*) Medea did not love her children; Medea was a mother; therefore, some mothers do not love their children. (A), (B), and (C) are similar in character, in that each subverts an acceptable belief by means of a conclusion based on acceptable beliefs. This produces a maximum of puzzlement because each of (1), (2), and (3) has had its contradiction shown to be also acceptable.

201. Reading ἀλλὰ πότερον.

202. Reading περὶ οὗ ὁ λόγος καὶ δι’ ὃ, καὶ μὴ προσλαβὼν τοῦτο.

something extraneous, it is by no means to be lightly despised; rather, the argument is decent, though the questioner has not asked his questions[203] correctly.

Also,[204] just as it is sometimes possible to propose a resolution in relation to the argument, sometimes in relation to the questioner and his mode of questioning, and sometimes in relation to neither of these, so too it is possible to question and deduce in relation to the posit, in relation to the answerer, and in relation to the time (when the resolution needs more time than[205] the present opportunity allows for dialectical argument leading to the[206] resolution).

34
Originality of the Study

As for how many and what sorts of things the fallacies that come about among dialectical interlocutors are based on, and how we are to prove the opponent to be saying something false and how to make him say something unacceptable, further, on what basis a solecism[207] comes about, how to ask questions, and what the arrangement of questions is, and, further, what all arguments of this sort are useful for, and about simply answering questions, both in general and as regards how to resolve arguments and solecisms,[208] let the foregoing be what we have to say. It remains to recollect our proposal at the start, say a few words about it, and bring our discussion to an end.

What we deliberately chose to do,[209] then, was to discover a certain capacity to argue deductively about the thing put before us on the basis of the things that are taken to be the most acceptable ones; for this is the work of dialectic itself and of the
183b1 examinational craft. But since there is provided along with it, because of its proximity to sophistry, not only the capacity of examining dialectically,[210] but also with a pretense of knowledge, because of this, we proposed for our study not only the work we just mentioned of being capable of getting hold of the relevant argument, but also, when submitting to argument, of defending our posit in the same manner through the most acceptable beliefs. And the cause of this we have stated, since this is also why Socrates used to ask questions and not answer them; for he used to acknowledge that he did not know.[211]

209. *Top*. 100a18–21.
210. Reading προκατασκευάζεται . . . ὥς οὐ μόνον πεῖραν δύναται. . . .
211. E.g., Plato, *Euthyphro* 5a, *Hippias Minor* 369d–e, *Republic* 337e–338a.

It has been made clear in the preceding discussion how many things this capacity will be related to and on how many it will be based,[212] and from what sources we will become well equipped with these, further, how questions must be asked and questioning generally arranged, and about the answers and resolutions related to deductions. And all the other issues have also been made clear that concern the same methodical inquiry about arguments. In addition, we have discussed fallacies in detail, as we have already stated previously.[213]

It is evident, then, that what was proposed has been adequately brought to an end. We must not overlook what has happened where this study is concerned. For in the case of all discoveries, those due to the previous labors of other people have been taken up and advanced bit by bit by those who took them up afterward, while original discoveries usually make progress that is small at first but is surely much more useful than what later develops from them; for perhaps the start is the most important thing of all, as the saying goes. That is why it is also the most difficult; for to the extent that it is greatest in capacity, it is smallest in magnitude and most difficult to see. But once it is discovered, it is easier to add to it and develop the rest in connection with it, which is precisely what has also in fact happened where rhetorical arguments are concerned, and also where pretty much all the other crafts are concerned. For those who discovered the starting-points advanced them in only a small way, while the ones who enjoy a good reputation nowadays are the heirs (so to speak) of a long series of predecessors who advanced it bit by bit, and in this way have developed it—Tisias coming after the first ones, Thrasymachus after Tisias, Theodorus after Thrasymachus, while numerous others have contributed numerous parts. That is why it is no wonder that the craft has a certain magnitude.

Of this study of ours, by contrast, it is not the case that part of it had been worked out before, while part had not. On the contrary, nothing existed at all. For in fact the education given by the paid teachers of contentious arguments was similar to the system of Gorgias; for while the one lot used to give [sets of] rhetorical arguments to learn by heart, the others gave arguments based on questions, into which questioner and answerer each thought that the arguments of both of them most often fell. That is precisely why the teaching they gave their students was rapid but un-craftlike; for they supposed that they could educate by imparting not the craft but its products, as if a person promising to impart a science dealing with having no pain in the feet were then to teach not the craft of shoemaking, or even from whom one will be able to be provided with such things, but were to provide numerous kinds of shoes of every variety; for he has helped supply one's need, but has not imparted a craft.

212. The reference, as at $183^{a}38$, is to the categories of predicates, and the premises or propositions constructible from them, discussed in *Top*. 1.4–9.
213. $183^{a}27$–28.

Also, where rhetorical arguments are concerned there were many things said long
184b1 ago, while about deductive argument we had absolutely nothing else earlier to speak of at all,[214] but were for a long time laboring and inquiring by knack.[215]

If, then, having gotten a theoretical grasp on it, it appears to us,[216] such being the situation as it existed at the start, that our methodical inquiry is adequate when compared with other studies that have developed on the basis of what has been handed
5 down, there remains for all of us, or rather for you,[217] the ones who listen to it, the work of showing sympathetic consideration for the shortcomings of our methodical inquiry and much gratitude for our discoveries.

BOOK 1

1.1
Scope and Method of Natural Science

Since in all methodical inquiries that have starting-points, causes, or elements, knowledge—that is, scientific knowledge—comes from knowledge of these (for we think that we know each thing once we know its primary causes and primary starting-points, all the way to its elements), it is clear that in the scientific knowledge of nature our first task must be to try to determine the things that concern the starting-points.

And the natural route is from things that are known and more perspicuous to us to things that are more perspicuous and better known by nature; for it is not the same things that are known to us and known unconditionally. That is why we must in this way advance from things that are less perspicuous by nature but more perspicuous to us to the things that are more perspicuous by nature and better known.

And the things that are in the first instance clear and perspicuous to us are to a degree confused. It is only later, through a division of these, that we come to know their elements and starting-points. That is why we must proceed from the universals to the particulars; for it is the whole that is better known by perception, and the universal is a sort of whole; for the universal embraces many things as parts. The same thing happens in a way with names in relation to their account; for **184^{b}10** a name like "circle" signifies a sort of whole in an indeterminate way, while the definition divides it into its particular [elements]. And children at first suppose[1] all men to be their fathers and all women their mothers, only later coming to distinguish each of them.

* Translated by C. D. C. Reeve. Text: W. D. Ross, *Aristotelis Physica* (Oxford, 1950), in consultation with P. Pellegrin, *Aristote Physique* 3rd ed. (Paris, 2021). The Greek title is *Phusikês Akroaseôs* (*Lectures on Natural Science*).

1. Reading ὑπολαμβάνει.

1.2
Natural Science's Starting-Points; Parmenides and Melissus

There must, then, be either one starting-point or several, and, if one, it must be either immovable, as Parmenides and Melissus say, or in movement, as the natural scientists say, of whom some state air to be the primary starting-point, others water.[2] But if there are several, they must be either limited in number or unlimited, and, if limited, but more than one, then either two, three, four, or some other number, while if there are an unlimited number, then either they are, as Democritus held, one in kind but differing in shape or in form,[3] and they may also be contraries.

Those who inquire about how many beings there are inquire in a similar way; for they are inquiring about the primary things of which the beings are composed, as to whether they are one or many, and if many, whether limited or unlimited in number. So they are inquiring primarily[4] about whether the starting-point and the element are one or many.

To investigate whether being is one and immovable is not to make an investigation concerning nature; for just as a geometer has no further argument against someone who does away with the starting-points [of geometry]—since this is a matter for another science[5] or one that is common to all[6]—so it is too in the case of starting-points [related to nature]; for there will no longer be a starting-point if being is one thing only, and one in this way. For a starting-point must be a starting-point of some thing or things.

To investigate, then, whether being is one in this way is like dialectically discussing any other thesis that is stated for the sake of argument, like that of Heraclitus,[7] or (if anyone were to state it) that being is one human being, or like refuting a contentious argument—which is precisely what the arguments of Melissus and Parmenides involve; for in fact they assume falsehoods and argue invalidly—or rather, the argument of Melissus[8] is crude and involves no puzzle. Grant him one absurdity and the others follow—nothing difficult in this.

As for ourselves, we must assume that the things that are by nature are in movement, either all of them or some of them. And this is clear from induction. At the same time, we should not resolve every [contentious argument] at hand, but those that involve false demonstration from the starting-points, and not those that do not.

8. 1.3.

For example, it belongs to the geometer to refute a quadrature by means of segments, but to refute one like Antiphon's does not belong to a geometer. Nonetheless, since Melissus and Parmenides happen to speak about nature, although the puzzles they state are not natural scientific ones,[9] perhaps it would be good to discuss them briefly; for the investigation involves philosophy.

The starting-point that is most proper of all [to such an investigation], since something is said to *be* in many ways, is to see in what way[10] those who maintain that all things are one say it. Do they mean that all are substance, or quantities, or qualities? And, again, do they mean that all are one substance—for example, one human being or one horse or one soul? Or quality, and that it is one—for example, pale, or hot, or something else of that sort? For these are all very different and all impossible to maintain. For if there is to be both substance and quality and quantity, then whether these are detached from each other or not, the beings will be many. If, on the other hand, everything is quality or quantity, then, whether substances exist or not, something strange results—if the impossible should be said to be [merely] strange! For none of the others is separable or beyond substance; for all of them are said of an underlying subject—the substance.

Melissus says that being is unlimited. Therefore, being is some quantity; for the unlimited is in [the category of] quantity, while a substance, quality, or affection cannot be unlimited except coincidentally, that is, if they were at the same time also quantities; for the account of the unlimited[11] makes use of quantity, but not of substance, or of quality either. If, then, there is substance and quantity as well, being is two, and not one. And if there is substance only, it is not unlimited, nor does it have any magnitude at all; for [if it did,] some quantity will have to exist.

Further, since things are said to be *one* in many ways, just as they are said to *be*, we must investigate in what way they maintain that the universe is one. Things are said to be one if they are continuous, or indivisible, or if the account of their essence is one and the same, like *methu* and *oinos*.[12]

Therefore, if continuous [is the relevant way of being one], then being[13] is many; for the continuous is divisible without limit.

There is, however, a puzzle about part and whole—although not perhaps relevant to the argument, but an intrinsic one—as to whether part and whole are one or several, and in what way one or several, and if several, in what way several. (And [the same puzzle arises] about parts that are not continuous.) Also, if each of two parts is one with the whole, as being indivisible from it, [there is the puzzle] that they will also be one with each other.

11. *Met.* $1066^{a}35$–$^{b}5$.
12. Terms for wine.
13. Reading πολλὰ τὸ ὄν.

But then if it is as being indivisible [that things are said to be one], then in nothing at all will there be a quality or a quantity, nor will being be unlimited, as Melissus says, or limited, as Parmenides does; for it is limits that are indivisible, not limited things.

But then if all beings are one in account, like clothing and apparel, then it follows that they are stating the Heraclitean argument;[14] for the being for good and for bad, for good and for not good, will be the same, so that to be good and to be not good, to be human and to be horse, will be the same, and their argument will be, not that all beings are one, but that they are nothing at all—and the being for such-and-such quality and for such-and-such quantity will be the same.

Even the more recent of the ancient thinkers were causing a disturbance lest the same thing should turn out to be both one and many at the same time. That is why some of them, like Lycophron, did away with the "is," while others remodeled the language, and said not "the human is pale" but "the human has paled," and not "the human is walking" but "the human walks," lest by adding "is" they would make the one be many—as if things were said to *be* or to be one in only one way. The beings, however, are many, either in account (for example, being for pale is distinct from being for musical, although the same thing may be both, and the one therefore many) or by division, like the whole and its parts. And at this point they were already involved in puzzles and agreeing that the one is many—as if it were not possible for the same thing to be both one and many, provided that these are not opposites; for a thing can be one either potentially or actually.

1.3
Refutation of Parmenides and Melissus

If we approach the thesis in this way, then, it appears to be impossible for the beings to be one. Also, the arguments on the basis of which these thinkers [try to] prove it are not difficult to refute. For both of them—both Melissus and Parmenides—contentiously deduce it.[15]

It is clear, indeed, that Melissus argues fallaciously;[16] for he thinks that if he has as an assumption that whatever comes to be has a starting-point, he also has that whatever has not come to be does not have one. Next, this also is absurd: to assume that in all cases there is a starting-point of the thing, not [merely] of the time, and not [merely] of unconditional coming to be, but of alteration as well—as if change never comes about all at once. Next, why is the universe immovable, if it is one? For if a part of it that is one—for example, this water here—can be moving within itself,

14. 185a7.
15. Omitting the repeat of 185a9–12.
16. *SE* 167b13–20.

why can't the universe also be moving within itself? Next, why should there be no such thing as alteration?

Moreover, being cannot be one in form either, except in the sense of what it is composed of (even some of the natural scientists speak of it as one in this, but not in the former, way); for human is distinct in form from horse, and contraries from each other.

And against Parmenides the ways of arguing—besides any that may be special to him—are the same. In fact, the resolution [of his argument] is in part that it is false and in part that it does not follow. It is false to the extent that he assumes that things are said to *be* in a simple way, while they are said to *be* in many ways. As for what does not follow, suppose that there are only pale things and that pale signifies one thing, nonetheless the pale things will be many and not one; for the pale will not be one by being continuous, nor by being one in account. For the being for pale will be distinct from the being for its recipient. And there will not be anything beyond the pale that is separable; for they are not distinct by being separable but because the being for pale and for what it belongs to are distinct. But this Parmenides did not get far enough to see.[17]

He must assume, then, not only that being signifies one thing, whatever it is predicated of, but also that it signifies precisely being and precisely one. For a coincident is said of some underlying subject, so that the thing of which being is a coincident will not be (for it is distinct from being); therefore, there will be something that is not. Precisely what is being, then, could not belong to something else. For it would not be possible for it to be a being, unless being signifies more than one thing, such that each is a sort of being. But it was assumed that being signifies one thing.

If, on the other hand, what is precisely being is not a coincident of other things, but other things are coincidents of it, why does precisely being signify being rather than not being? For suppose that what is precisely being will also be pale, but the being for pale is not precisely being (for even being cannot be a coincident of pale; for what is not precisely being will not be), then the pale will not be—and not in the sense of not being something-or-other, but of not being anything at all. Therefore, what is precisely being will not be; for it is true to say that it is pale, but this signified not being.[18] So even pale signifies precisely being. Therefore, being signifies more than one thing.

Therefore, being will not have magnitude either, if indeed being is precisely being; for the being of each of the two components would be distinct.

That what is precisely being is divided into another thing that is precisely being is evident even from the [definition of an] account. For example, suppose the human is

17. *Met.* $987^{b}32–33$, $1078^{b}25$.

18. (1) Pale ≠ what is precisely being, since it is a coincident of it. (2) The being for pale ≠ what is precisely being. (3) Being = what is precisely being (explicit at $186^{b}13$). (4) The being for pale ≠ being. (5) The pale is not (a being). (6) Precisely what is being is pale. (7) Precisely what is being is not (a being).

something that is precisely being, then the animal is also something precisely being, as is the two-footed. For if they are not something that is precisely being, they will be coincidents, either present in the human or in some other subject. But this is impossible; for something is said to be a coincident either if it is such that it can belong or not belong [to that subject], or if that to which the coincident belongs is present in the account of it (for example, being seated is a coincident as separable, while in the [account of the] snub[19] the account of the nose with which we say the snub is coincident belongs). Further, whatever is present in the definitional account of something, or of which the account is composed, must be such that in the account of it the account of the whole thing is not present—for example, in the two-footed that of the human, or in the pale that of the pale human. Therefore, if this is the way things are, and if the two-footed is a coincident of the human, then either it must be separable from the human, so that it would be possible for the human not to be two-footed, or else the account of the human would be present in the account of the two-footed. But this is impossible; for the latter is present in the account of the former.

If, on the other hand, the two-footed and the animal are coincidents of something else, and if each of them is not precisely a sort of being, then the human too would be a coincident of something else. But we must take it that what is precisely being is not a coincident of anything at all, and that if both of two things are said of something, that which they compose must be said of it as well. Therefore, the universe will be composed of indivisibles.

Some thinkers did, in fact, give in to both arguments: to the argument that all things will be one if being signified one thing, when they posited that not being exists; and to the argument from the division into two things, when they posited indivisible magnitudes.[20]

But it is evident that it is not true that if being signifies one thing, and not at the same time the contradictory of this, then not being will not exist; for nothing prevents not being from not being something, but [only] from simply not being. And it is absurd to say that if nothing else exists beyond being itself, then all things will be one. For who [can] get to know being itself except by knowing that what is precisely

19. *Met.* 1025ᵇ30–34.

20. (1) What is precisely being = the human (186ᵇ15–16). Hence (2) we cannot take the human to be a coincident of something else X, since then it would not be identical to X, and there would be more than one being, what is precisely being and X. But the human = the animal + the two-footed. So if the human were a coincident of X, then (3) the animal and the two-footed would also be coincidents of X. So these have the same status as the human and as what is precisely being, and so are distinct beings. If they do not have definitional accounts, we can stop there, since they will be indivisibles. If they do have definitional accounts, eventually these too must bottom out in indivisibles. Hence what is precisely being will eventually bottom out in as many indivisible beings as its definitional account makes reference to when fully spelled out. But the universe = what is precisely being (185ᵇ7). Hence (4) the universe will be composed of indivisibles.

being is something? And if that is so, there is nothing to prevent beings from being many, as was stated.

That it is impossible for being to be one in the way claimed, then, is clear.

1.4
The Views of the Natural Scientists

The natural scientists, on the other hand, state things in two ways. Some make being,[21] what underlies, one body—either one of the three or something else[22] that is denser than fire and rarer than air—and then generate the other things, making them many by means of condensation and rarefaction. These are contraries, which taken universally are excess and deficiency,[23] as are the great and the small in Plato,[24] except that he makes these be matter, and the one be form, while they make the underlying one be matter and the contraries be differences, that is, forms.

Others say that the contrarieties are present in the one and are segregated out of it—for example, Anaximander speaks like this, as do those, such as Empedocles and Anaxagoras, who say that the beings[25] are one and many; for they too segregate out the others from the mixture. They differ from each other, however, in that Empedocles posits a cycle of mixings and segregations, while Anaxagoras posits that it happened once, and Anaxagoras posits an unlimited number both of uniform things and of contraries, while Empedocles posits the so-called elements only.

Anaxagoras seems to think that these are unlimited in this way because he accepted as true the common belief of the natural scientists that nothing comes to be from not being (for it is because of this that they say that "all things were together" and that he makes the coming to be of such-and-such a sort of thing an alteration, while they make it aggregation and disaggregation).

Further, there is the fact that contraries come to be from each other. Therefore, they must have been there from the start; for if everything that comes to be must do so either from beings or from non-beings, and if it is impossible for it to come to be from non-beings (and in this belief all those concerned with nature are agreed), they regarded the remaining alternative as immediately following by necessity, that things come to be from beings that are already present but that, because of the smallness of their volume, from beings that are imperceptible to us.

That is why they say that everything has been mixed together in everything: because they saw everything coming to be from everything. But things appear different from one another, and are called by distinct names, depending on what is **187^{b}1**

21. Reading ὂν.
22. It is unclear who held this view, also mentioned at *GC* $328^{b}35$, $332^{a}21$, *Met.* $988^{a}30–31$.
23. *Met.* $1042^{b}31–35$.
24. $209^{b}33–210^{a}2$.
25. Reading τὰ ὄντα.

numerically predominant throughout the mixture of the unlimited particles; for they say that no whole thing is purely pale, dark, sweet, flesh, or bone, but whichever it has most of is what seems to be the nature of the thing.

If the unlimited, insofar as it is unlimited, is unknowable,[26] then the unlimited in number or with respect to magnitude is an unknowable quantity, and the unlimited in form is an unknowable quality. If, then, the starting-points are unlimited both in number and in form, it is impossible to know what results from them. For we think we have got hold of knowledge of a composite when we know the things it is composed of and what their quantity is.

Further, if it is necessary for a thing, of which a part can be of any size whatever in the direction of greatness and of smallness, to be itself capable of being so (by "parts" I mean components present in the whole into which the whole is divided), and if, on the other hand,[27] it is impossible for an animal or a plant to be of any size whatever, in the direction of greatness and of smallness, then it is evident that none of its parts can be either; for [if they could,] so likewise could the whole. But flesh and bone and things of that sort are parts of an animal, and fruits are parts of plants. It is clear, therefore, that it is impossible for flesh or bone or any other such thing to be of any size whatever, either in the direction of greatness or in the direction of smallness.

Further, if all such things are already present in each other, and do not come to be but instead, being present within, are segregated out; and if they are called [what they are] after whatever there is more of; and if anything can come to be from anything (for example, if water can be segregated out from flesh, and flesh from water); and if every limited body is done away with by [subtracting] some limited body: it is evident that it is not possible for everything to be present in everything. For if flesh is subtracted from water, and if this is done again by segregation from what remains, even if the flesh subtracted is always smaller, nonetheless it will not be smaller than a certain magnitude. So if the process of segregation comes to a stop, not everything will be present in everything (for there will be no flesh in the remaining water); but if it does not come to a stop, but subtraction is always possible, there will be an unlimited number of equal limited parts in a limited magnitude. But this is impossible.

In addition to these considerations, if every body from which something is subtracted must become smaller, and if flesh is definite in quantity, both in greatness and in smallness, it is evident that from the smallest possible quantity of flesh no body can be segregated out; for otherwise there will be a quantity of it smaller than the smallest possible one.

Further, in each of the unlimited bodies there would be already present unlimited flesh, blood, and brain, not indeed separated from each other, but beings nonetheless, and each unlimited. But this is unreasonable.

26. *Met.* 994b21–31.
27. Reading δὲ.

The statement that segregation will never [be complete] is not made on the basis of knowledge, but it is correct; for affections are inseparable. If, then, colors and states were mixed together, if they got segregated out, there would be a pale or a healthy that is not another thing, and is not predicated of a subject either. So [Anaxagoras'] *nous* is absurd, since it is seeking impossible things, if indeed it wishes to separate them, although it is impossible to do this, both with respect to quantity and with respect to quality: with respect to quantity, because there is no smallest magnitude; with respect to quality, because affections are inseparable.

Nor is Anaxagoras correct even about the coming to be of things of the same form. For there is a way in which clay is divided into clays, and a way in which it is not.

Moreover, the way in which bricks come from a house and a house from bricks is not the same as the way in which water and air are and come from each other. Also it is better to assume a smaller number of starting-points, that is, a limited number, precisely as Empedocles does.

1.5
The Starting-Points Are Contraries

All thinkers, then, posit contraries as starting-points, both those who say that the universe is one and not moving (for in fact Parmenides posits hot and cold as starting-points, though he calls[28] them by the names "fire" and "earth") and those who make use of the rare and the dense. Also, Democritus, who posits plenum and void (saying that the one is present as being, the other as not being), but further posits position, shape, and order. And these are kinds of contraries—for example, of position, up and down, in front and behind; of shape, angular and angle-less, straight and curved.

It is clear, then, that all in some way posit contraries as starting-points. And this is reasonable; for the starting-points must come neither from each other nor from other things, and all things must come from them. And to the first contraries these features belong: because they are first, they do not come from other things, and because they are contraries, they do not come from each other.

But how this conclusion follows must also be investigated by appeal to argument. Let us first take it, then, that no being whatever is by nature such as to do or suffer any random thing due to any random thing, nor does anything come to be from just anything, except if one takes a coincidental case; for how could pale come to be from musical, unless musical were coincident with the not pale or with the dark? Instead, pale comes from not pale—and not from any not pale but from dark, or something intermediate between the two. And musical comes to be from not musical—except **$188^{b}1$**

28. B8 DK.

not from any not musical but from unmusical, or something intermediate between the two, if there is such.

Nor again do things pass away into the first random thing—for example, the pale does not pass away into the musical, except sometimes coincidentally, but into the not pale, and not into any random one but into the dark or the intermediate. Similarly, the musical passes away into the not musical, and not into any random one but into the unmusical or into some intermediate, if there is such.

It is also the same in all other cases, since the same account also holds of the beings that are not simple but composite. But because the opposite dispositions have no names, its taking place escapes notice. For in all cases the harmonious must come to be from the unharmonious and the unharmonious from the harmonious, and the harmonious must pass away into the unharmonious, and not into any random one but into the opposite one. And it makes no difference whether we speak of harmony, order, or composition; for it is evident that the account is the same. Moreover, a house too, and a statue, and any other such thing whatever comes to be in the same way; for the house comes to be from the non-combination, or rather division, of these things in this way,[29] and the statue, or anything else that is shaped, comes to be from shapelessness. And each of these things is, on the one hand, an order, and, on the other hand, a sort of composition.[30]

Therefore, if this is true, everything that comes to be comes to be from, and everything that passes away passes away into, its opposite or an intermediate. But the intermediates are [composed] of contraries—for example, colors from black and white.[31] So all the things that come to be by nature are either contraries or [composed] of contraries.

Up to this point most of the others pretty much followed along with us, as we said previously;[32] for they all posit the elements and the things they call "starting-points" as contraries, even if they do so without argument, as if compelled by the truth itself. But they differ among themselves in that some take contraries that are prior, some contraries that are posterior, some contraries that are better known by reason, others that are better known by perception; for some posit hot and cold as the causes of coming to be, others wet and dry, others odd and even or strife and love, and these differ from each other in the way just stated.

So the starting-points they stated are in one way the same, in another way distinct—distinct in the way that most people believe; the same insofar as they are analogous; for they are taken from the same column of contraries,[33] some of which encompass [others], while others are encompassed. In this way, then, they spoke of them as similarly and distinctly, better and worse, and some as better known by

29. *Met.* 1036b23–24, 1043a7–9.
30. I.e., a form or a matter-form compound.
31. *Met.* 10.7, *Sens.* 439b25–30.
32. 188a19–30.
33. *Met.* 986a22–26.

reason, as was said previously, others by perception (for the universal is known by reason, the particular by perception; reason is of the universal, while perception is of the particular)—for example, the great and the small are known by reason, the rare and the dense by perception.

It is evident, then, that starting-points must be contraries.

1.6
The Number of Starting-Points (1)

We must next say whether they are two, three, or more in number. For they cannot be one, because contraries are not one, and they cannot be unlimited, because [if they were,] being would not be scientifically knowable.[34] Moreover, in any one kind there is just one contrariety,[35] and substance is one specific kind, and because it is possible [to generate everything] from a limited number [of starting-points], it is better to do so from a limited number, like Empedocles, than from an unlimited one (for Empedocles thinks that he gives an account of all things just as Anaxagoras does from the unlimited ones). Further, some [pairs of] contraries are prior to others, and some come to be from others,[36] such as sweet and bitter, white and black, while the starting-points must remain always. It is clear from these considerations that they are neither one nor unlimited in number.

Since, then, the starting-points are limited in number, there is some reason not to make only two of them; for one might raise the puzzle as to how density could at all be by nature such as to affect rarity, or rarity density. And similarly for any other contrariety whatever; for it is not love that gathers strife together and makes something from it, nor does strife do so from love, but both affect a third distinct thing. And some thinkers assume more than one such thing from which they construct the nature of the beings.

And in addition to this, if no nature distinct from the contraries is assumed, one may also raise this further puzzle; for we never in fact see contraries constituting the substance of the beings, but what is a starting-point must not to be something that is said of an underlying subject. For if it is, there will be a starting-point of the starting-point; for the underlying subject is a starting-point, and seems to be prior to what is predicated of it. Further, we say[37] that substance is not contrary to substance. How, then, can substance come from what are not substances? Or how could what is not substance be prior to substance?

That is why, if someone considers both the former argument and this one to be true, he must, if he is going to preserve both, posit some third thing that underlies

34. 187ᵇ7–8.
35. *Met.* 10.4.
36. Reading ἐξ ἄλλων.
37. *Cat.* 3ᵇ24–27.

189ᵇ1 [the contraries], like the one spoken of by those who say that the universe is one nature, such as water or fire or what is intermediate between the two. What is intermediate seems more [of a starting-point]; for fire, earth, air, and water are already involved with contrarieties.[38] That is why indeed those who make the underlying subject something distinct from these—or the ones who of these elements make it air—make it so not without reason; for of these air has indeed the least perceptible differences, and after it, water. Yet all these thinkers give shape to this one thing by means of contraries, that is, by means of density and rarity and the more and the less. And these taken generally are clearly excess and deficiency, as was stated previously.[39] Indeed this belief too—that the one and excess and deficiency are starting-points of the beings—would seem to be an ancient one, except that it is not stated in the same way. The ancient thinkers made excess and deficiency do the affecting and the one be affected, while some of the more recent ones stated the contrary instead, that the one does the affecting and the two the being affected.

There would seem, then, on the basis both of these and other such considerations, that there is some reason to think that the elements are three in number, as we said, but no longer any to think that there are more than three; for one is sufficient for being affected, while, if there are four, there will be two contrarieties, and a separate intermediate nature will be needed for each. If, on the other hand, being [just] two, they can generate things out of each other, then one of the two contrarieties would be superfluous. Moreover, it is impossible for there to be more than one first contrariety. For substance is one kind of being, so that the starting-points can differ only in being prior or posterior to each other, and not in kind; for in any one kind there is always one contrariety, all the other contrarieties seeming to be referred back to one.

It is evident, then, that the elements are neither one in number, nor more than two or three—but whether they are two or three involves, as we said,[40] much puzzlement.

1.7
The Number of Starting-Points (2): Our Own Account

We will now give our own account, first discussing all cases of coming to be; for the procedure that is in accord with nature is first to say what is common to all cases, and then to get a theoretical grasp on what is special to each one.

For we say that one thing comes to be from another, indeed, a distinct one from a distinct one, whether speaking about simple things or about compound ones. I mean this: it is possible for the human to come to be musical, and it is possible for the not musical to come to be musical or for the not musical human to come to be a musical **190ᵃ1** human. By "a simple thing that comes to be [something]," then, I mean the human

38. *GC* 330ᵃ30–ᵇ7.
39. 187ᵃ16–17.
40. 189ᵃ21, ᵇ17.

and the not musical, and by "a simple thing that [something is] coming to be" I mean the musical. By "a compound one" I mean both the thing that comes to be and the thing that comes to be it, whenever we say that the not musical human comes to be a musical human.

In some of these cases we say not only that this comes to be something but that it comes to be from something—for example, musical from not musical—but we do not say it in all cases; for musical does not come from human, but rather a human came to be musical.

Among things that come to be [something] that we called the "simple" ones, some remain when they come to be [that thing], while others do not; for the human remains and is human when he comes to be musical, while the not musical and the unmusical, whether simple or compound, do not remain.

Having made these distinctions, there is this to grasp from every case of coming to be, provided we look at them in the way we described, that there must always be some underlying subject, what comes to be [something], and even if it is one in number, in form it is not one (by "in form" I mean the same as in account); for the being for the human is not the same as the being for the unmusical. And the one remains and the other does not remain. The thing that is not an opposite remains (for the human indeed remains), but the not musical and the unmusical do not remain, and nor does the thing composed of both—for example, the unmusical human.

We say that something comes to be from something, and not that it comes to be something, chiefly in the case of what does not remain—for example, that musical comes to be from unmusical, but not that it does so from human. Nonetheless, we do sometimes also speak in this way about what does remain; for we say that a statue comes from bronze, not that the bronze comes to be a statue. As for what comes to be from what is opposite and does not remain, we speak of it in both ways, saying both that it comes to be from something and that it comes to be something; for we say both that from unmusical it comes to be musical and that the unmusical comes to be musical. That is why we also say the same about the compound; for we say both that from an unmusical human the musical human comes to be and that the unmusical human comes to be musical.

Since things are said to come to be in many ways, and some things are said not to come to be but to come to be a this something, while only substances are said to come to be unconditionally, it is evident that, in the other cases, by contrast, there must be some underlying subject that comes to be (for in fact when a quality, a quantity, a relative to something else, a time[41] or a place comes to be, it is of some underlying subject, because a substance is the only thing that is never said of any other underlying subject, while all the others are said of a substance).

41. Reading καὶ ποτὲ.

190ᵇ1 But that substances and the other[42] things that are unconditionally beings also come to be from an underlying subject will become evident on investigation. For in every case there is something that underlies, from which the thing comes to be—for example, plants and animals come to be from seed. And among the things that unconditionally come to be, some do so by change of shape (for example, a statue), some by addition (for example, things that grow), some by subtraction (for example, [the statue of] Hermes from the stone), some by composition (for example a house), some by alteration (for example, things changing with respect to their matter). And it is evident that everything that comes to be in this way comes to be from an underlying subject.

So it is clear from what has been said that whatever comes to be is always composite, and there is, on the one hand, one thing that comes to be, and, on the other, the thing that the former comes to be. And the latter is twofold: either the underlying subject or the opposite. By "the opposite" I mean, for example, the unmusical, and by "the underlying subject," the human; and the lack of figure, the lack of shape, or the lack of order is the opposite, while the bronze, the stone, or the gold is the underlying subject.

It is then evident—if indeed there are causes and starting-points of the beings that are by nature, from which they primarily are or have come to be, not coincidentally but each the thing that is said to be in accord with its substance—that everything comes to be from both the underlying subject and the shape; for the musical human is composed in a way of human and musical; for resolutions of its account[43] are into the accounts of these two. It is clear, then, that whatever comes to be, comes to be from these things.

The underlying subject, however, though one in number, is two in form; for, on the one hand, there is the human, the gold, and, in general, the countable matter, which is more a this something, and it is not coincidentally that what comes to be comes to be from it; on the other hand, there is the privation (that is, the opposite), which is coincident. And the form is one—for example, the order, the musicality, or anything else predicated in this way.

That is why we must say that in one way there are two starting-points, and in another way that there are three. And in one way the contraries are starting-points—for example, if we say they are the musical and the unmusical, the hot and the cold, or the harmonious and the unharmonious. But in another way they are not, for contraries cannot be affected by each other.[44] [The resulting puzzle] is also resolved due to the fact that the underlying subject is something else; for it is not a contrary.

So in a way the starting-points are no more numerous than the contraries, but are (one might almost say) two in number, yet not two in every way either (because the

42. Retaining ἄλλα.
43. Reading διαλύσεις γὰρ τὸν λόγον.
44. 189ᵃ20–26.

being for them is distinct), but rather three; for the being for the human and for the musical are distinct, as are the being for the lack of shape and the being for bronze. **191ᵃ1**

How many starting-points there are of natural beings that come to be, then, and in what way they are so many, has now been stated. And it is clear that there must be something to underlie the contraries, and that the contraries must be two in number. In another way, this is not necessary; for just one of the contraries, by its absence and presence, is sufficient to produce the change. 5

As for the underlying nature, it is scientifically knowable by analogy. For as the bronze stands to the statue, the wood to the bed, or as what lacks a shape before it gets its shape stands to anything else that has a shape, so the underlying nature stands to a substance, a this something, and a being. 10

This, then, is one starting-point, although it is neither one nor a being in the way a this something is; another one, the account;[45] and a further one is the contrary of this: the privation. In what way these are two, and in what way more, has been stated above.

First, then, it was stated[46] that only the contraries were starting-points, later, that it was necessary for there also to be something else to underlie them, and for the starting-points to be three. And from what we have said just now it is evident what the differentia of the contraries is,[47] how the starting-points stand to each other, and what the underlying subject is. But whether the form or the underlying subject is substance is not yet clear. However, that the starting-points are three, in what way they are three, and what mode [of being] they have, is clear. From these considerations, then, we should be able to get a theoretical grasp on how many starting-points there are and what they are. 15 20

1.8
A Puzzle of the Ancient Thinkers Solved

We will next argue that this is also the only way to resolve the puzzle of the ancient thinkers. For those who were the first to inquire philosophically about the truth and the nature of beings were turned aside, and, as it were, diverted from their route, by their inexperience,[48] and say that none of the beings either comes to be or passes away, because what comes to be must come to be either from what is or from what is not, both of which are impossible; for what is cannot come to be (for it already is), while from what is not nothing can come to be; for there must be[49] some underlying 25 30

45. Reading μία δὲ ὁ λόγος.
46. 189ᵃ9–10, ᵃ33–ᵇ1.
47. I.e., that one is the lack or privation of the other.
48. In dialectic.
49. Reading δεῖ.

subject [for it to come from]. And developing the consequences of this, then, they went on to say that there is no plurality of things but only being itself.

They embraced this belief, then, because of the foregoing considerations. We, on the other hand, say that the claim that something comes to be from what is or from what is not, or that what is not or what is affects something or is affected or comes to be something of whatever sort, is in one way no different from the claim that the **191b1** doctor affects something or is affected, or that something is or comes to be from a doctor. So, since we say this latter thing in two ways, it is clear that we also say in two ways that [something comes to be] from what is and that what is affects or is affected.

A doctor builds a house not insofar as he is a doctor but insofar as he is a builder, and comes to be pale not insofar as he is a doctor but insofar as he is dark. But he cures and comes to be ignorant of medicine insofar as he is a doctor. So, since we in the strictest sense say that a doctor acts on something, is affected by something, or comes to be something from being a doctor, when it is insofar as he is a doctor that he acts on it, is affected by it, or comes to be it, it is clear that to say that something comes to be from what is not also signifies this: coming to be from it insofar as it is what is not.

The ancient thinkers abandoned the puzzle through failing to make this precise distinction, and, because of their ignorance of it, added so much more ignorance to it that they thought that nothing else comes to be or is [besides being itself], and thus did away with all coming to be whatever.

We too say, as they do, that nothing unconditionally comes to be from what is not, but that things do, nonetheless,[50] come to be from what is not—for example, coincidentally (for a thing comes to be from the privation, which is intrinsically something that is not, and which is not a constituent of the thing that results; but this causes wonder, and it seems impossible that anything could come to be in this way from what is not).

Similarly, there is no coming to be either from what is or of what is, except coincidentally. But in that way this too can come about, in the same way as, for example, if animal comes to be from animal, and a certain sort of animal from a certain sort of animal. For example, if dog came to be from horse.[51] For the dog would come to be not only from animal of a certain sort, but also from animal, although not insofar

50. Reading ὅμως.

51. Rejecting the addition of ἐκ κυνὸς ἢ ἵππος. What we are to do is consider an entirely imaginary case of dog coming to be from horse in keeping with the embryology of *GA* 768b5–12, so as to distinguish the kind *animal* (common to dog and horse) from its various forms (*dog*, *horse*) in a vivid way. At a certain stage in the embryological development of the imaginary dog it is already animal, due to the relevant movements in the male progenitor's seed having already been transferred to the female menses. Subsequently, it becomes an animal of a certain sort, but it does not do so from animal insofar as it is animal, since it is already that (hence, "exists already" at 191b22–23). Indeed, if it were to become an animal of a certain sort from animal insofar as it is animal, it would surely become a horse. That it becomes a dog shows that it is not from (the kind) animal that its being a dog derives. Hence it is not from (the "kind") what

as it is animal; for that exists already. But if a certain sort of animal is to come to be, not coincidentally, it will not be from animal, and if a certain sort of thing that is is to come to be, it will not be from a thing that is, nor from a thing that is not. For we have said[52] what "from what is not" signifies: from what is not insofar as it is what is not.

Further, we also do not do away with [the principle that] everything either is or is not.

This, then, is one way [of resolving the puzzle], but there is another in that the same things can be said either with respect to the capacity or with respect to the activity. But this has been discussed with more exactness elsewhere.[53]

So, precisely as we have said, the puzzles due to which people are compelled to do away with some of the things we mentioned are now resolved; for this is why the earlier thinkers too were so much diverted from their route in the case of coming to be, passing away, and change generally; for if they had apprehended this nature,[54] all their ignorance would have been dissolved.

1.9
More on Starting-Points

Other thinkers, indeed, have touched on this, but not adequately. For, in the first place, they agree that a thing comes to be unconditionally from what is not, and that on this point Parmenides spoke correctly. And then it appears to them that if this **192^a1** nature is one in number, it is also one in potentiality, which is a very different thing.

For we say that matter and privation are distinct, and that one of these, the matter, coincidentally is not, while the privation intrinsically is not, and that the matter is even close to being—in a way is—substance, while the privation[55] is in no way substance. The other thinkers, by contrast, identify what is not with the great and the small alike, whether taken together or separately. So their three things[56] and ours are entirely distinct. For they got so far as to see that there must be some underlying nature, but they make it one; for even if someone[57] makes it a dyad, calling it "the great and the small," he still does the same; for he overlooks the other nature.[58]

---

is (= being) or what is not (= not being) that a certain sort of thing that is (= a certain sort of being) comes to be.

55. Reading στέρησιν.

56. The great, the small, and the one (187^a17–18).

57. Plato.

58. The privation.

For the nature that remains is a joint cause, together with the shape, of the thing that comes to be, just as a mother is, while the other part of the contrariety might often appear, if thought is focusing intensely on its production of bad effects,[59] not to be at all. For we say that there is one thing that is divine, good, and sought after, and a second that is contrary to the first, and a third that naturally yearns for the first and, in accord with its own nature, strives for it, while it follows on their view that the contrary strives for its own destruction. And yet the form cannot yearn for itself, because it is not in a state of need, and neither does the contrary (for contraries are destructive of each other), instead it is the matter that does the yearning, just as female yearns for male and shameful for noble—except not the intrinsically shameful, but the coincidentally so,[60] and not the intrinsically female, but the coincidentally so.[61]

In one way too the underlying nature passes away and comes to be, and in another way it does not. For as that "in which," it does intrinsically pass away (for what passes away—the privation—is present *in* it); but as what is potentially, it does not intrinsically pass away, but must be incapable of passing away and coming to be. For if it came to be, there must have been some first underlying subject from which it came to be and is present in it. This is the [material] nature itself, so that it will be before coming to be [which is impossible]. (For by "matter" I mean the first underlying subject of each thing from which it comes to be and which is present in it non-coincidentally.) And if it passes away, it will come to this [material nature] at last, so that it will have passed away before it has passed away [which is also impossible].

To make an exact determination about the starting-point in terms of form, whether it is one or many, and what it is or they are, is the work of primary philosophy, so it may be set aside till the appropriate time comes for that.[62] But about the
192b1 forms of things that are natural and capable of passing away, we will speak in the expositions that follow.

That there are starting-points, then, what they are, and how many in number they are, we may take to be determined in the foregoing way. Let us now proceed after first making a fresh start.

59. Cases of passing away, destruction, and death, which may be attributed to a sort of not being (present of form) (*Met.* 1013b11–15).

60. The noble is associated with "order, proportion, and definiteness" (*Met.* 1078b1). Since these are formal elements, this is a case of matter (some underlying subject that is coincidentally shameful) yearning for form (nobility).

61. What is coincidentally female is the material element in reproduction (the menses or female seed), and what it "yearns for" in yearning for male is, again, the formal element.

62. *Met.* 7–9, 12.

BOOK 2

2.1
What Nature Is and What It Is to Be by Nature

Among the beings, some are by nature, while others are due to other causes. Those that are by nature are animals and their parts, plants, and the simple bodies—for example, earth, fire, air, and water (for we say that these and things like them are by nature). All these things manifestly differ from things that are not composed by nature. For each of them has within itself a starting-point of moving and being at rest—some with respect to place, some with respect to increase and decrease, others with respect to alteration.

A bed, by contrast, or a cloak, or anything else of that kind, insofar as each such predicate applies to it—that is, to the extent that it is a product of craft—has no innate impulse to change. But insofar as it is coincidentally made of stone, earth, or a mixture of the two, to that very extent, it does have one. This is because nature is a sort of starting-point and cause of moving and being at rest in that to which it belongs primarily, intrinsically, and not coincidentally. (I say "not coincidentally" because, for example, someone, being a doctor, might come to be a cause of health to himself. Nonetheless, it is not insofar as he is made healthy that he possesses the craft of medicine, but rather being a doctor and being made healthy are coincident in the same person. That is why they are usually separated from each other.)

It is the same way with other things that are produced; for none of them has within itself the starting-point of its production, but in some cases (such as a house and each of the other artificial things) the starting-point is in something else and external, while in others (those that may be coincidental causes to themselves) the starting-point is in them, but not intrinsically.

Nature, then, is what has been stated. And things that have this sort of starting-point have a nature. And each of them is a substance; for they are a sort of underlying subject, and a nature is always in an underlying subject. And these things are also in accord with nature, as too is whatever belongs intrinsically to them, as spatial movement upward belongs to fire; for this neither is nor has a nature but is by nature and in accord with nature. **193^{a}1**

What nature is, then, what is by nature, and what in accord with nature, has now been stated. That there is such a thing as nature it would be ridiculous to try to prove; for it is evident that there are many beings of the relevant sort. And to prove what is evident by means of what is not evident is characteristic of someone who cannot judge what is known by means of itself and what is not known by means of itself (and it is not unclear that this can happen to someone; for someone who was born blind may deduce things about colors). So for such people it is necessary for the argument to be about [mere] names, while they understand nothing.

It seems to some people that the nature and substance of each of the beings that are by nature is the first component present in it, which is intrinsically unshaped—for example, the wood is the nature of the bed, and the bronze of the statue. It is a sign of this, Antiphon says, that if someone were to bury a bed, and the decomposing material were to acquire the capacity to send up a shoot, what came up would not be a bed but wood—his supposition being that the disposition of the material that is in accord with convention and craft knowledge belongs coincidentally to the wood, while the substance is what in fact remains continuously while these things happen to it. And if each of these materials is also related to another in the same way (for example, bronze and gold to water, bones and wood to earth, and similarly too with anything else whatever), then that would be their nature and substance.

That is why some people say that fire is the nature of the beings, some that earth, air, or water is, some that some of them are, and others that all of them are. For whatever any of these people took to be of this sort—whether it was one or more than one—this or these he declared to be the substance in toto, everything else being affections, states, or dispositions of these, and declared this or these to be eternal (for they do not change from themselves), while other things come to be or pass away an unlimited number of times.

In one way, then, something is said to be nature when it is the first underlying matter for each of the things that have within themselves a starting-point of movement and change.

In another way, what is said to be nature is the shape—that is, the form—that is in accord with the account. For just as something is said to be [a work of] craft when it is in accord with craft knowledge and produced by craft, so something is said to be [a work of] nature when it is in accord with nature and produced by nature. And as in the one case we would not yet say that a thing is at all in accord with craft if it were only potentially a bed and had not yet the form of a bed, or that it is [a work of] craft, so it is in the case of things composed by nature; for what is only potentially
193b1 flesh or bone, before it acquires the form that is in accord with the account by which we define flesh or bone and say what it is, neither has yet its own nature nor is it by nature. So in this other way the nature of things that have within themselves a starting-point of movement is the shape, that is, the form, which is not separable except in account. (What is composed of both [form and matter] is not nature, but by nature—for example, human being.)

In fact, the form is more nature than the matter is; for each thing is said to be when it actually is more than when it potentially is.

Further, human comes to be from human, but not bed from bed. That in fact is why some people say that the shape is not the nature but the wood, because if it were to send up a shoot, it would not be a bed that comes up but wood. But if the wood

is therefore nature, the shape too is nature; at any rate,[63] human comes to be from human.

Further, when we speak of nature as coming to be,[64] it is as a route to nature [as possessed]. For it is not said of things in the way medical treatment is, which is a route not to the craft of medicine but to health; for medical treatment must proceed from the craft of medicine and not to it. But it is not in this way that nature (*phusis*) [as coming to be] is related to nature [as possessed], rather what is naturally growing (*to phuomenon*), insofar as it is naturally growing, proceeds from something to something. What is it, then, that is growing? Not the thing it is growing from, but the one it is growing into. The shape, therefore, is nature.

But something is said to be shape or nature in two ways; for the privation too is in a way form. Whether or not there is a privation and a contrary involved in unconditional coming to be, however, we must investigate later.[65]

2.2
Natural Science Distinguished from Mathematics and First Philosophy

Since we have distinguished the number of ways in which things are said to be nature, the next thing is to get a theoretical grasp on how the mathematician differs from the natural scientist (for natural bodies too have planes, solids, lines, and points, which are the things the mathematician investigates). Further, on whether astronomy is distinct from natural science or a part of it; for if it belongs to the natural scientist to know what the sun or the moon is, for him not to know their intrinsic coincidents would be absurd—especially since it is evident that those who speak about nature discuss the shapes of the sun and the moon, and in particular whether the earth and the cosmos are spherical or not.

The mathematician too busies himself about these things, although not insofar as each of them is the limit of a natural body, nor does he get a theoretical grasp on the coincidents of natural bodies insofar as they are such. That is why he separates them; for they are separable from movement by the understanding, and so their being separated makes no difference, nor does any falsehood result from it.

Those who speak about the Forms do this too, though it escapes their notice; for they separate natural objects though these are less separable than mathematical ones. This would become clear if one were to try to state the definitions both of the objects themselves and their coincidents. For odd and even, straight and curved, and further, number, line, and figure will be without movement, while flesh, bone, and human will not, but rather all of them are said of things just as snub nose is and not as curved is. This is also clear from the more natural-science-like parts of mathematics, such as

63. Reading γ'.
64. *Met.* 1014^{b}16–17.
65. 5.1, *GC* 1.3.

optics, harmonics, and astronomy; for these are in a way the reverse of geometry. For while geometry investigates natural lines, but not insofar as they are natural, optics investigates mathematical lines, but not insofar as they are mathematical, but rather insofar as they are natural.

But since nature is [said of things] in two ways, form and also matter, we must get a theoretical grasp on it as if we were investigating what snubness is, so that we must get a theoretical grasp on natural things neither without their matter nor with regard to their matter [alone]. For of course there might be also a puzzle about this, since there are two natures, as to which is the concern of the natural scientist. Or is he concerned with the combination of the two? But if with the combination of the two, he is also concerned with each of them. Does it belong to the same science, then, or to distinct ones, to know each of them?

If we look to the ancient thinkers, natural science would seem to be concerned with matter [alone] (for it was only very slightly that Empedocles and Democritus touched on form and essence).

If, on the other hand, craft imitates nature, and if it belongs to the same science to know the form and, up to a point, the matter (for example, it belongs to the doctor to know health, and also bile and phlegm, in which health resides, and to the builder to know the form of a house, and also the matter, that it is bricks and beams, and similarly in the case of the others), then it belongs to the natural scientist to know both natures.

Further, knowledge of the for-the-sake-of-which—that is, the end—belongs to the same science as knowledge of the things that are for its sake. But nature is an end and a for-the-sake-of-which (for whenever a continuous movement has a certain end of its movement, this is a last thing[66] and the for-the-sake-of-which; that is why the poet[67] spoke ridiculously when he said, "he has reached the [bad] end for which he was born," since by "end" we mean not every last thing, but the best one). For the crafts produce their matter, some unconditionally, while others make it good relative to the work.[68] And we make use of all things as if they were there for us (for we also are in a way an end; for the end is twofold,[69] as was said in *On Philosophy*[70]).

There are two crafts that rule over the matter and have knowledge of it, the craft **194b1** concerned with the use and the architectonic one concerned with production. That is why the one concerned with the use is in a way architectonic, but it differs from the other insofar as it knows the form, although the architectonic one as productive[71] knows the matter; for the captain knows and prescribes what sort of form the rudder must have, while the other knows what sort of wood it must be made from and by

71. Reading ἡ δὲ ἀρχιτεκτονικὴ ἡ ὡς ποιητική.

what movements it will be made. In the case of the products of craft, then, it is us who produce the matter for the sake of the work, while with natural things the matter is already present.

Further, matter is relative to something; for there is one [sort of] matter for one form, and another for another.

Up to what point, then, must the natural scientist know the form and the what-it-is? Or just as the doctor knows sinews and[72] the blacksmith bronze, is it in fact[73] up to the point of knowing what each of them is for the sake of, and knowing about the ones that, though separable in form, are in matter? For human is begotten by human and sun.[74] But the way the separable is, and what it is, is the work of primary philosophy to determine.

2.3
What Sorts of Causes There Are and in What Way They Are Causes

Having determined these things, we must investigate how many and what sorts of causes there are. For since our study is undertaken for the sake of knowledge, and we do not think we have knowledge of each thing until we have grasped the why of it, which is to grasp its primary cause, it is clear that we must also do this in the case of coming to be, passing away, and every sort of natural change, so that by knowing the starting-points of these we may try to refer back to them each thing we are inquiring about.

Something is said to be a cause if it is the component from which a thing comes to be—for example, the bronze of a statue or the silver of a bowl, and also the kinds of these. The form or paradigm, that is, the account of the essence, and kinds of this (for example, of the octave, the ratio 2:1 and number in general), and the parts included in the account. Further, that from which the change or rest from change first starts—for example, the person who has deliberated is cause [of the action] and the father of his child and, in general, the producer is cause of the thing being produced and the change-maker of what is changed. Further, the end, and this is the for-the-sake-of-which—for example, of taking walks health is the end; for why does he take walks? In order that he may be healthy, we say. And in speaking that way we think we have presented the cause. Also, anything, then, that comes to be as an intermediate before the end, when something else has started the movement—for example, in the case of health, making thin, purging, drugs, or instruments; for all these are for the sake of the end, although they differ from each other in that some **195^{a}1** are works and others instruments.

72. Reading καὶ.
73. Retaining γὰρ.
74. *GC* 336^{a}23–^{b}10, *Met.* 1071^{a}13–17.

These, then, are pretty much all the ways in which things are said to be causes, and because they are said to be such in many ways it follows both that there are many causes of the same thing, and not coincidentally (as, for example, a statue has both the craft of sculpture and the bronze as causes—not in accord with its being another thing[75] but insofar as it is a statue—although not in the same way, but the one as matter and the other as that from which the movement derives), and that things can be causes of each other (as, for example, exercise [is a cause] of good physical condition and the latter of exercise, although not in the same way, but the one as end and the other as the starting-point of movement). Further, the same thing can be the cause of contraries; for the thing that, when present, is cause of so-and-so, we sometimes hold causally responsible, when absent, for the contrary—for example, the cause of a shipwreck is the absence of the captain whose presence was a cause of its preservation.

All the causes now mentioned fall into four most evident ways [of being causes]. For phonetic elements[76] are causes of syllables, matter of artifacts, fire, and all such things, of bodies, the parts of the whole, and the hypotheses[77] of the conclusion, as being causes in the sense of that from which. And of these some are causes as underlying subject (for example, the parts), some as the essence (for example, the whole, the mode of composition, and the form). And the seed, the doctor, the deliberator, and, in general, the producer are all starting-points from which comes change or rest. The remainder are causes as the end and the good of other things; for what other things are for the sake of tends to be the best and their end. Let us assume that it makes no difference whether we say good or apparent good.

These, then, are the causes and this is the number of their forms, but the ways of being causes, though many in number, also come under comparatively few headings. For things are said to be causes in many ways, and those within the same form are said to be prior or posterior to each other—for example, [as a cause] of health, the doctor and the craftsman; of the octave, the double and number; and in every case the encompassing causes and the particular ones.

Further, there are coincidental causes and their kinds—for example, [as a cause of] a statue, in one way Polyclitus, in another a sculptor, because the sculptor coincides with Polyclitus, and, as examples of what includes the coincidental cause, a human is a cause of the statue, or, in general, an animal (because Polyclitus is human and a human is an animal). And among coincidental causes some are more remote than others, some less—for example, if the pale and the musical were said to be causes of the statue.

Beyond[78] all the things said to be causes either properly or coincidentally, however, some are said to be so potentially, others actively—for example, [as a cause of] the house's being built, a builder, on the one hand, and a builder building, on the other.

75. I.e., not in a coincidental way.
76. Phonetic elements in spoken syllables are roughly equivalent to letters in written ones.
77. Here premises, which need not be hypothetical in status.
78. Reading παρὰ.

Similarly, the things that causes are causes of will also be said to be in the ways mentioned—for example, this statue, a statue, or, in general, a likeness, or this bronze, bronze, or, in general, matter; and similarly in the case of coincidental [effects].

Further, both the proper and the coincidental may be said to be causes in combination—for example, not Polyclitus or sculptor but Polyclitus the sculptor.

But still all of these things are [just] six in number, each said to be in two ways: either as the particular, as the kind, as the coincidental, or as the kind of the coincidental is, or as these are either as combined or as taken simply, and all of them either actually or potentially. But they differ to the extent that what is actual and what is particular exists, or does not exist, at the same time as the things it causes—for example, this person curing at the same time as this one recovering his health, this builder building with this building being built. But this is not always the case with what are potentially causes. For the house does not pass away at the same time as the builder.

Here, as in the other cases, we must always seek the most precise cause of each thing (for example, a human is building because he is a builder, and the builder is building in virtue of the craft of building; this latter, therefore, is the prior cause, and similarly in all cases).

Further, we must seek kinds of causes for kinds of things, and particular causes for particular things—for example, a sculptor is the cause of a statue, and this sculptor of this statue. And we must seek potential causes for potential effects, and actual causes for actual effects.

Let these determinations suffice, then, as to the number of causes and to the ways in which they are causes.

2.4
Luck and Chance as Causes

But luck and chance are also said to be causes, and many things are said to be and to come to be because of luck or because of chance. We must investigate, then, in what way luck and chance are included among the causes [we distinguished], whether luck or chance are the same or distinct, and, in general, what luck is and what chance is.[79]

For some people raise a puzzle as to whether luck or chance exist or not; for they say that in fact nothing comes to be by luck, but that everything that is said to come to be by chance or luck has some definite cause—for example, of someone's coming into the marketplace by luck and finding the person he wished but did not expect to meet, they say that the cause is his wishing to go shopping in the marketplace. And similarly in the case of other things that are said to come to be by luck, they say that it is always possible to find some thing—not luck—that is the cause, since if there were indeed such a thing as luck, it would appear truly strange and puzzling that none

79. $198^{a}2$–5, $197^{a}36$–$^{b}37$, 2.6.

of the ancient wise men who talked about the causes of coming to be and passing away ever determined anything about luck. On the contrary, it seems that they also thought that nothing is by luck. But this too is cause for surprise; for many things come about and are by luck and by chance, and, though people are not unaware that each of the things that come to be can be referred back to some [definite] cause (as the argument just given[80] says that does away with luck), nonetheless they all speak of some of these things as being by luck, others as not being by luck. That too is why the early wise men should have mentioned luck in some way or other.

But then they did not think either that luck was among the causes [they recognized]—for example, love, strife, understanding, fire, or anything else of that sort. Either way, then, it is strange, whether they supposed that there was no such thing as luck, or that there was such a thing but neglected to discuss it. Especially when they sometimes make use of it, as Empedocles does when he says that air is not always separated out on top but as luck would have it. At any rate, he says in his cosmogony that "it happened to run in this way then, but often in another way."[81] And he says that most of the parts of animals come to be by luck.

Other people[82] make chance the cause of this heaven and of all the cosmoses; for they say that the vortex came to be by chance, as did the movement that separated things out and put in place the present order of the universe. And this itself merited yet more surprise; for, on the one hand, they say that animals and plants neither are nor come to be by luck, but that nature, understanding, or something else of that sort is the cause (for it is not just any random thing that comes to be from a given sort of seed, but an olive tree from one sort and a human being from another), while, on the other hand, they say that the heaven and the most divine of visible things came to be by chance, and have no cause of the sort that animals and plants have. And yet if such is the case, this very fact merits attention, and something might well have been said about it. For in addition to the other respects in which what they say is strange, it is even stranger to say it when they see nothing in the heaven coming to be by chance, while among the things that [in their view] are not by luck many do come to be by luck. And yet for the contrary to happen would surely have been likely.

There are others,[83] though, who believe that luck is indeed a cause, but that it is unclear to human thought, as being a divine thing and very daimonic. So we must investigate what chance is and what luck is, whether they are the same or distinct, and how they fit into the causes distinguished.[84]

2.5
How Luck and Chance Are Causes

In the first place, then, since we see that some things always come to be in the same way, and others do so for the most part, it is evident that luck or what is by luck is not the cause of either of these—either of what is by necessity and always or of what is for the most part. But since there are other things beyond these that come to be, which everyone says come to be by luck, it is evident that there is such a thing as luck and as chance; for we know that things of this third sort are by luck and that things that are by luck are things of this sort.

Among things that come to be, some do so for the sake of something, while others do not (and of the former, some are in accord with deliberate choice, while others are not in accord with deliberate choice, although both are among the things that are for the sake of something), so it is clear that among the things beyond those that are necessary or for the most part, there are some that admit of being for the sake of something. The ones that are for the sake of something are ones that might come to be as a result of thought or of nature. Whenever, then, something like this comes to be coincidentally, we say that it does so by luck (for just as being is either intrinsic or coincidental, in the same ways it is possible to be a cause—for example, the intrinsic cause of a house is what has the craft of building, but coincidentally it is the pale or the musical; and while the intrinsic cause is definite, the coincidental one is indefinite; for an unlimited number of things may coincide in one thing).

As has been said,[85] then, whenever a coincidental cause occurs among things that come to be for the sake of something, then they are said to be by chance or luck. (The difference between the two will be determined later;[86] but for now let us take as evident that both are found among things that are for the sake of something.)

For example: The man would have come for the sake of getting back his money when a debtor was collecting contributions for a feast, if he had known about it. But in fact he did not come for the sake of this. On the contrary, it was a coincidence that he came,[87] and [as if he] did so for the sake of getting back his money—this provided that he neither for the most part nor of necessity frequents that place. The end, however, getting back his money, although it is not one of the causes present in him, is among the things that can be deliberately chosen and are a result of thought. **197^{a}1** And in this case he is then said to have come there by luck. But if he had deliberately chosen, and for the sake of getting back his money, or if he always or for the most part frequented the place, then it was not by luck that he did so.

It is clear, therefore, that luck is a coincidental cause that is found among those of the things that are for the sake of something and in accord with deliberate choice.

85. 196^{b}23–24.
86. 197^{a}36–^{b}37.
87. Secluding αὐτῷ.

That is why thought and luck are concerned with the same things; for deliberate choice does not occur without thought.

The cause of things that might come to be by luck are of necessity indefinite. That is why luck too seems to be something indefinite and unclear to human beings, and why it might seem that in a way nothing comes to be by luck. For all these things are said correctly, that is, reasonably. For things do in a way come to be by luck; for they come to be coincidentally, and luck is a coincidental cause. Unconditionally, luck is not the cause of anything. For example, although a builder is cause of a house, coincidentally a pipe player is. And of the man's coming and getting back his money, though he did not come for the sake of this, the coincidental causes are unlimited in number; for in fact he might have come because he wished to see someone, to be an accuser or defendant in court, or to go to the theater.

Also, it is correct to say that luck is something beyond reason; for a reason is about what always is or for what for the most part is, and luck is found in what is beyond these. So, since the causes in such cases are indefinite, luck too is indefinite.

Nevertheless, in some cases one might raise a puzzle as to whether any random thing might be a cause of what is [by] luck—for example, of health, the wind, or the heat of the sun, but not having had a haircut. For some coincidental causes are more closely relevant than others.

Luck is said to be good when something good results, bad when something bad results, and is called "being lucky" or "being unlucky" when the results are of some magnitude. That is why someone who comes within a hair's breadth of a great evil or a great good is said to be lucky or to be unlucky, because thought speaks as if the thing were already had; for by a hair's breadth seems no distance at all.

Further, it is reasonable that good luck is unstable; for luck is unstable; for nothing that is by luck can be either always or for the most part the case.

Both luck and chance, then, are coincidental causes, as was said, that are found among things that admit of coming to be neither unconditionally nor for the most part, and, of these, among the ones that happen for the sake of something.

2.6
Luck and Chance Defined and Distinguished

They differ in that chance extends more widely; for everything that is by luck is by chance, but not everything that is by chance is by luck. For luck and what is by luck
197b1 belong to whatever good luck and, in general, action also belong. That is why luck is of necessity concerned with what is doable in action. A sign of this is that good luck seems to be the same as happiness or close to it, and happiness is a sort of action; for it is doing well in action. So whatever cannot do an action cannot do anything by luck either.

And it is because of this that no inanimate object, wild beast, or child does anything by luck—because they do not have deliberate choice. Nor do good luck or bad luck belong to them, except in virtue of some similarity—as Protarchus said that the stones from which altars are made have good luck, because they are esteemed, while their fellows are trodden underfoot. Nevertheless, even these things are affected by luck in a way, when someone doing some action concerning them does so by luck, but otherwise they are not.

Chance, on the other hand, is found both in the other animals and in many inanimate objects—for example, the horse came by chance, we say, in that it was saved because it came, but did not come in order to be saved. And that the tripod fell [on its feet] is a case of chance; for, though it stood that way for the sake of being sat on, it did not fall for the sake of being sat on.

So it is evident that among things that unconditionally come to be for the sake of something, whenever those that come to be do not do so for the sake of what actually results, the cause being external, we say that they come to be by chance. And we say that the ones that come to be by luck are the ones among those that come to be by chance that can be deliberately chosen by those having deliberate choice.

A sign of this is the term "pointless," because it is said of something when what it is for the sake of does not come to be, but [only] what was for that thing's sake.[88] For example, suppose walking is for the sake of loosening the bowel, if this did not come about when someone has walked, we say that the person walked pointlessly and that his walking was pointless. The supposition being that this is what is pointless: what is naturally for the sake of something else, when it does not accomplish what it was—and is by nature—for the sake of. For if someone said that his washing himself was pointless because the sun was not eclipsed, he would be ridiculous; for the one was not done for the sake of the other. It is chance, then, as even its name (*automaton*) suggests, when a thing (*auto*) comes to be pointlessly (*matên*). In fact, the stone that fell did not do so for the sake of hitting the man; it was by chance, therefore, that the stone fell, because it might have fallen due to someone and for the sake of hitting someone.

The separation of chance from luck is greatest in things that come to be by nature; for if something comes to be contrary to nature,[89] we say that it came to be not by luck but rather by chance. But even this is distinct from chance; for the cause of the latter is external, that of the former internal.

What chance is, then, what luck is, and in what respect they differ from each other, has now been stated. And as for the way in which they are causes, each of them **198^{a}1** is a starting-point from which movement originates; for each is always a cause of what is either by nature or a result of thought, although their number is indefinite.

88. Reading τὸ οὗ ἕνεκα, ἄλλ' ὃ.
89. *Met.* 1032^{a}28–32, 1034^{b}4–6.

But since chance and luck are causes of things of which either understanding or nature might have been the cause, whenever something comes to be a coincidental cause of these same things, and as nothing coincidental is prior to what is intrinsic, it is clear that neither is the coincidental cause prior to the intrinsic one. Therefore, chance and luck are posterior to understanding and nature. So however true it may be that chance is the cause of the heaven, understanding and nature must be prior causes both of many other things and of this universe.[90]

2.7
The Natural Scientist Must Know All Four Causes

It is clear, then, that there are causes and that they are as many in number as we stated;[91] for the why of things encompasses that many; for the why is referred back at last to the what-it-is, in the case of immovable things (for example, in mathematics; for there it is referred back at last to the definition of straight, commensurable, or something else); or to the first cause of movement (for example, why did they go to war?—because they were raided); or to what it is for the sake of (for example, in order that they may rule); or, in the case of things that come to be, to the matter. It is evident, then, that these are the causes and this is how many they are.

But since the causes are four in number, the natural scientist must know them all, and to give the why in a natural scientific way must refer it back to all of them—the matter, the form, the cause of movement, the for-the-sake-of-which. But the last three often amount to one; for the what-it-is and the for-the-sake-of-which are one, and the first source of the movement is the same in form as these (for a human begets a human), and so it is, in general, in the case of things that cause movement by being in movement.

Those that cause movement without being in movement, by contrast, are no longer part of natural science; for they do not cause movement by having a movement or a starting-point of movement within themselves, but are immovable. That is why there are three sorts of [scientific] studies,[92] one concerned with immovable things, one concerned with movable ones that are incapable of passing away, and one concerned with things that are capable of passing away.

So the why is given by referring back to the matter, the what-it-is, and the first cause of the movement. As a matter of fact, in the case of coming to be one investigates the causes most of all in this last way: by asking, what comes to be after what, what first affected or was affected, and in this way always going on to the next one in the series.

90. 196[a]24–26.
91. 194[b]23–195[a]3.
92. *Met.* 6.1.

The starting-points of natural movement are twofold. One of these is not natural; for it does not have a starting-point of movement within itself. Anything is of this sort if it causes movement without being itself in movement, just as what is entirely **198b1** immovable (that is, the first of all beings) does and also the what-it-is (that is, the shape); for it is the end and the for-the-sake-of-which. And so, since nature is for the sake of something, this cause must also be known and the why must be given in all ways—for example, from this that will necessarily result (whether from it 5 unconditionally or for the most part); if this is going to be [then that must first be so] (as from the premises the conclusion results); this is the essence; because it is better this way (not unconditionally better, but better in relation to the substance of each given thing).

2.8
Does Nature Act for an End?

We must first state, then, why nature is among the causes that are for the sake of 10 something, and then about necessity and what way it is present in natural things; for everyone refers things back to this latter cause, stating that since the hot, the cold, and each thing of this sort, then, is by nature such-and-such, certain other things of necessity are and come to be; for in fact if they mention any other cause, they just touch upon it, and let it go at that—one[93] mentioning love and strife, another the 15 [divine] understanding.[94]

There is thus a puzzle as to what prevents nature from acting not for the sake of something or because it is better, but as Zeus rains down rain[95]—not in order that the wheat may grow, but of necessity (for what has been drawn up must become cold, and what has become cold, having become water, must come down; but the growing of the wheat when this happens is coincidental). Similarly, if someone's wheat on 20 the threshing floor perishes, it does not rain for the sake of this, that the wheat may perish, but rather this is coincidental. So what is to prevent parts in nature too from being the same way (the front teeth, for example, of necessity growing out sharp and suitable for tearing apart, the molars broad and useful for grinding up nourishment), 25 inasmuch as they do not come to be for the sake of the given thing, but rather it was coincidental—and similarly with the other parts in which there seems to be the for-the-sake-of-which? Wherever, then, all the parts came to be just as if they had come to be for the sake of something, then the things [whose parts they were] survived, as a result—although by chance—of being suitably composed, while those that were not 30

93. Empedocles.
94. Anaxagoras.
95. An idiomatic way of saying, "it rains."

like that, such as the man-headed ox-progeny mentioned by Empedocles,[96] perished and continue to perish [when produced].

This is the argument, then, and any others that may be like it, that might raise a puzzle. But it is impossible for things to be like this. For these things we mentioned and all things that are by nature come to be as they do either always or for the most part, but none of the things that are by luck or chance does so. For it does not seem to be by luck or by coincidence that it rains often in winter, but if it does so in the dog days of summer; nor that there are heat waves in the dog days, but if there are in the winter. If, then, things seem to be either by coincidence or for the sake of something, and if these ones are neither by coincidence nor by chance, then they would be for the sake of something. But surely all such things are by nature, as even those who state the foregoing argument would say. The for-the-sake-of, then, is present in things that come to be and are by nature.

Further, in whatever has an end, it is for its sake that the things that come before, and the ones following them in order, are done in action. Then as things are done in action, so they are in nature, and as they are in nature, so each of them is done in action, provided there is no impediment. In action, things are done for the sake of something. Therefore, in nature too they are for the sake of something. For example, if a house were one of the things that came to be by nature, it would do so just as it now does by craft. And if things came to be not only by nature but also by craft, they would come to be just as they do by nature. One thing, therefore, is for the sake of another. In general, craft in some cases completes the things that nature is incapable of bringing to completion, while in others it imitates nature. If, then, what is in accord with craft is for the sake of something, it is clear that what is in accord with nature is as well; for in what is in accord with craft and in what is in accord with nature the relation of what comes after to what comes before is the same.

This is most evident in the case of the other animals, since they do not make things either by craft, by carrying out inquiries, or by engaging in deliberations—which is why some people are puzzled as to whether spiders, ants, and things of that sort do what they do by means of understanding or of some other capacity. And if we proceed a little further in this way, it is evident that even in plants things come to be that further the end—for example, leaves for the sake of shading the fruit. If, then, it is both by nature and for the sake of something that the swallow makes its nest and the spider its web, and if plants grow leaves for the sake of the fruit, and send roots down rather than up for the sake of nourishment, it is evident that this sort of cause is present in things that come to be and are by nature. And since nature is twofold, the one as matter and the other as shape, and since the latter is an end, and the other things are for the sake of the end, the shape must be the cause, the cause in the sense of the for-the-sake-of-which.

96. B61 DK.

Error, however, occurs even in what is in accord with craft (for grammarians have written incorrectly and doctors given the wrong medicine), so it is clear that it is also possible in what is in accord with nature. If, then, it sometimes happens in things that are in accord with craft that the for-the-sake-of-which is correct, and that in cases of error what is attempted is for the sake of something but fails to hit it, the same must also be so in the case of natural things, and monstrosities must be errors of the for-the-sake-of-which. Among the things composed at the start as well, therefore, the [man-headed] ox-progeny, if they were unable to reach a certain defining mark and end, must have come to be as a result of some defective starting-point, in just the way that, as things stand, they do so from defective seed.

Further, seed must come to be first, and not immediately the animals, and the "first whole-natured kind"[97] was a seed.

Further, the for-the-sake-of-which is also present in plants, though in a less articulated way. Among plants too, then, did olive-headed vine sprouts come to be, just as man-faced ox-progeny did, or did they not? For that would be absurd. But surely they would have to have, if indeed this also happened among the animals.

Further, among seeds too coming to be would have to be a matter of luck [on this view]. But the person who says this does away entirely with what is by nature and also with nature; for things are by nature when, from some starting-point within themselves, they arrive by a continuous movement at a certain end—from a given starting-point, though, the same thing is not reached in each case, nor is some random one, yet [the movement] is always to the same thing, provided there is no impediment.

The for-the-sake-of-which, and what is for its sake, might come to be by luck. We say, for example, that a guest-friend came by luck, paid the ransom, and then went away, when he did the action as if he had come for the sake of doing it, though it was not for the sake of doing it that he came. And so this is coincidental (for luck is one of the coincidental causes, as we said previously[98]). But when something comes to be always or for the most part, it does not do so coincidentally or by luck, but in what is natural it always does so in this way, provided there is no impediment.

It is absurd to think that a thing does not come to be for the sake of something, if the mover is not seen deliberating. For even craft does not deliberate;[99] and if the craft of shipbuilding were present in the wood, it would produce in the same way as nature. So, if the for-the-sake-of-which is present in craft, it is also present in nature. This is clearest when a doctor cures himself; for nature is like him.

It is evident, then, that nature is a cause, that is, one in the way that the for-the-sake-of-which is a cause.

97. Empedocles B62.4 DK.
98. 196b23–27.
99. Cf. *NE* 1112a34–b9.

2.9
The Necessity in Natural Things

As for what is by necessity [in natural things], we must ask whether it is hypothetical,
35 or also unconditional. For as things stand it is thought that what is by necessity is found in the coming to be in the way in which someone might suppose that the wall
200a1 of a house came to be by necessity, because heavy things by nature spatially move downward, and light ones upward. And so the stones and the foundations are down below, the earth is up above them because it is lighter, and the wooden logs are on the very top, for they are lightest. Nonetheless, though the wall does not come to be
5 without these, it did not in fact come to be because of them, except as matter, but rather for the sake of shelter and protection.

It is the same way in the case of all the other things in which the for-the-sake-of-which is present: although they could not come to be without things that have a necessary nature, they do not in fact come to be because of these, except as matter, but rather for the sake of something. For example, why is a saw such as it is? So
10 that this may be, and for the sake of this. But in fact it is impossible that this thing that the saw is for the sake of should come to be, unless the saw is made of iron. It is necessary, therefore, for it to be made of iron, if there is to be a saw and its work. The necessity, then, is hypothetical, but not [necessary] as an end; for the necessity lies in the matter, while the for-the-sake-of-which lies in the account.

15 The necessity found in mathematics and in things that come to be in accord with nature are in a way much the same; for since the straight is this, it is necessary that the angles of a triangle equal two right angles, but not the other way around—even though if the latter does not hold, the straight will not be this either. In things that come to be for the sake of something it is the reverse: if the end is or will be, the
20 previous things are or will be too, and just as in mathematics, where if the conclusion does not hold, the starting-point will not either, so here if the previous things are not or will not be, then neither will the end—that is, the for-the-sake-of-which. For the end is itself also a starting-point, although not of action but rather of rational calculation (and in mathematics the starting-point is the starting-point of the rational calculation; for there are no actions involved).

And so if there is to be a house, it is necessary for these things to come to be or to
25 be present, and, in general, the matter that is for the sake of something—for example, bricks and stones if there is to be a house. Yet the end does not exist because of these, except as matter, nor will it exist because of them. In general, however, if they are not present there will be neither house nor saw (in the case of a house if the stones are not present, in the case of a saw if the iron is not), just as in mathematics the starting-points will not hold if the triangle does not have [its interior angles equal to] two right angles.

30 It is evident, then, that the necessity in natural things is what is called "matter" and "the movements of the matter." And the natural scientist must state both causes,

but most of all the for-the-sake-of-which; for this is the cause of the matter, not the matter of the end. And the end is the for-the-sake-of-which and the starting-point springing from the definition and the account, as in the things that are in accord with craft—since a house is such-and-such sort of thing, these things must come to be or be present of necessity, or since health is this, these things must come to be or be present of necessity; and similarly if a human is this, these must be, and if these, these others. Presumably, necessity is also present in the account; for if the work of sawing is defined as such-and-such sort of division, it will not occur unless the saw has teeth of such-and-such a sort, and these cannot be of such-and-such a sort unless the saw is made of iron. For even in the account there are parts that stand as matter of the account.[100]

BOOK 3

3.1
Movement (1)

Since nature is a starting-point of movement and change, and our methodical inquiry is concerned with nature, we must not overlook what movement is; for if we are ignorant of this, we are necessarily ignorant of nature too. And once we have made determinations about movement we must try to inquire in the same way about the things that come next in order.

Movement seems to be one of the things that are continuous, and the unlimited first comes to light in what is continuous. That is also why those who define the continuous often make use of the account of the unlimited as well, on the supposition that what is divisible without limit is continuous. In addition, it seems that without place, void, and time, it is impossible for there to be movement.

Clearly, then, both because of this and because these things are common to everything [in nature] and universal, we must first undertake to investigate each of them (for the theoretical investigation of what is special is posterior to that of what is common). And first, as we said, we must investigate movement.

Some things, then, are actual only, others potential, others potential and actual,[101] being either a this something, a quantity, a quality, or likewise one of the other categories of being. Of what is relative, one sort is said of things with reference to excess and deficiency, another with reference to affecting and being affected, and, in general, with reference to what can move something and be moved; for what can move

100. $194^{a}12–15$.

101. Respectively, a substantial form, such things as the unlimited and the void, and matter-form compounds. Reading τὸ μὲν ἐντελεχείᾳ μόνον, τὸ δὲ δυνάμει, τὸ δὲ δυνάμει καὶ ἐντελεχείᾳ.

something can move what can be moved, and what can be moved can be moved by what can move it.

There is no movement beyond the things; for what changes always does so either with respect to substance, quantity, quality, or place, and we say there is nothing to take as common to these that is neither a this, nor a quantity, nor a quality, nor a place, nor any of the things in the other categories either; so there is no movement or change of anything beyond the ones we mentioned, since not even a being exists beyond the ones we mentioned.

Each of these belongs to everything in two ways—for example, the this (for in the one case it is shape, in the other its privation), with respect to quality (for in the one case it is white, in the other black), with respect to quantity (which in the one case is complete, in the other incomplete). It is the same way with respect to spatial movement, which in the one case is upward, in the other downward—alternatively, in the one case [of] what is light, in the other [of] what is heavy. So there are just as many forms of movement and change as there are of being.

Since there is a distinction with respect to each kind between actuality and potentiality, the actualization of what is potentially, insofar as it is such, is movement—for example, the actualization of the alterable, insofar as it is alterable, is alteration, the actualization of what is capable of increasing and of its opposite, decreasing (for there is no name common to both) is increasing and decreasing, the actualization of what is capable of coming to be and passing away is coming to be and passing away, and the actualization of what is capable of spatial movement is spatial movement. That movement is this is clear from the following: whenever what is buildable, insofar as it is what we say it is, is in actuality, it is being built, and this is building. And similarly with learning, curing, rolling, leaping, maturing, and aging.

Since, in some cases, the same things are both potential and actual, although not at the same time or in the same respect, but instead, for example, are actually hot and potentially cold, already it follows that many things will both affect each other and be affected; for everything of this sort will be at once capable of affecting and being affected. And so what naturally causes movement will itself be movable; for everything of this sort causes movement being itself moved. Some people even think that whatever causes movement is itself moved, but how things stand with regard to this will become clear from other considerations[102] (for there is one mover that is immovable[103]).

The actualization of what is potentially, when it is actually active, not insofar as it is itself but insofar as it is movable, is movement. By "insofar as" I mean this: The bronze is indeed potentially a statue, but nonetheless it is not the actualization of the bronze, insofar as it is bronze, that is movement; for the being for bronze is not the same as the being for something potentially movable, since if it were unconditionally

102. 8.5.

103. Reading τι τῶν κινούντων.

the same in account, the actualization of the bronze, insofar as it is bronze, would be movement. But, as was said, it is not the same (this is clear in the case of contraries; for to have the potential to be healthy and to have the potential to be sick are not the same—for in fact if they were, to be sick and to be healthy would be the same—though the underlying subject, whether it is healthy or diseased, whether it is moisture or blood, is one and the same). And since it is not the same, just as color and the visible are not the same either, it is evident that it is the actuality of the potential, insofar as it is potential, that is movement.

It is clear, then, that movement is this, and that it takes place when the actuality itself exists, and neither earlier nor later; for each thing [of this sort] admits of sometimes being active, sometimes not—for example, the buildable: the activation of the buildable, insofar as it is buildable, is building (for the activity is either this—the building—or the house). But when the house exists, what is buildable no longer exists: what is buildable is what is being built. It is necessary, therefore, for building to be the activity, and building is a sort of movement. And the same account also applies in the case of the other movements.

3.2
Movement (2)

That what was stated is correct is also clear from what others say about movement and from the fact that it is not easy to define it otherwise. For we cannot put movement and change in some other kind either. This is clear if we investigate where some people[104] put them, saying that movement is otherness or inequality or not being. But none of these—neither things that are other than something, nor things that are unequal, nor things that are not—is necessarily in movement, nor is change to these or from these, any more than to or from their opposites.

What causes people to posit movement as these is that it seems to be something indefinite, and the starting-points in one of the two columns of opposites, because they are privations, are indefinite; for none of them is either a this or a such-and-such sort or any of the rest of the categories. The cause of movement's seeming to be indefinite is that it cannot be posited unconditionally[105] either as a potentiality of beings or as an activation of them; for neither the thing that is potentially of a certain quantity nor what is actively of a certain quantity is necessarily moved, and movement seems to be a sort of activity, but incomplete activity. The cause of this is that the thing that is potentially, of which it is the activation, is incomplete. And because of this it is difficult to grasp what movement is; for it must be posited either as a privation or as a potentiality or as an activity that is unconditionally such. But manifestly none of

104. Plato, *Timaeus* 57e–58a.
105. Reading ἁπλῶς.

these is possible. And so the remaining option is that it must be the way we said, that
202^a1 it is a sort of activity, but the sort of activity we stated,[106] which, though difficult to discern, can exist.

Everything that moves things in the way stated[107] is also moved, that is, every mover that is potentially movable and whose immobility is rest (for in the case of what movement belongs to, its immobility is rest). For to affect this sort of thing, insofar as it is of this sort, is just what it is to move it. But this it does by contact, so it is at the same time affected. That is why movement is the actualization of the movable, insofar as it is movable, and this happens by contact with what is capable of moving it, so that the latter is also affected at the same time. The mover, however, is always the bearer of some form, whether a this, or of this quality, or of this quantity, which will be the starting-point and cause of movement, whenever it moves something—for example, what is actually a human being makes, from what is potentially a human being, a human being.

3.3
Mover and Moved

Also, a point that raises a puzzle: it is evident that movement is in the thing moved. For movement is the actualization of the movable by what can in fact[108] move something. And the activation of what is capable of moving something is no other than this; for there must be the actualization of both; for it can move something by having the potentiality to do so, and it is moving it by being active. But it is on the movable that the mover is capable of acting, so that the activation of both alike is one, just like the interval between one and two and between two and one, or the hill up and the hill down; for these things are one, but their account is not one; and similarly in the case of the mover and the moved.

This involves a logico-linguistic puzzle; for presumably there must be some activation of what is capable of affecting and of what is capable of being affected, the first of which is an affecting, the second a being affected; and the work and end of the first is a thing done,[109] while of the second it is a thing undergone. Since, then, both of these are movements, if they are distinct, what are they in? For either they are both in what is affected and moved, or else the affecting is in what affects and the being affected is in what is affected (if this too must be called an "affecting," then affecting will be homonymous).

Moreover, if this is so, the movement will be in the mover (the same account will apply to the mover and to the thing moved), and so either every mover will be moved,

106. 201^a10–11.
107. 201^a23–25.
108. Retaining καὶ.
109. *Met.* 1050^a21–22.

or, while possessing movement, it will not be moved. If, on the other hand, both the affecting and the being affected are in what is moved and affected, and teaching and learning, which are two things, are in the learner, then first the activation of each will not be in each, and second, and absurdly, [the learner] will be moved with two movements at the same time; for what will be the two alterations of one thing and [tending] toward one form? But that is impossible.

But, then, the activation of each will be one. But [some will say] it is unreasonable for two things that are distinct in form to have one and the same activation. Also, if **202b1** teaching and learning, and affecting and being affected, are the same, then to teach will be the same as to learn, and to affect will be the same as to be affected, so that it will be necessary for the one who is teaching to be in every case learning, and the one that is affecting to be in every case affected.

Or, is it rather that it is not absurd for the activation of one thing to be in another thing—for teaching is the activation of the one who can teach, but occurring in something, and not cut adrift, but of this occurring in that; nor is there anything to prevent the activation of two things from being one and the same (not as the same in being, but in the way that what is potentially is related to what is actively); nor is it necessary for the one who is teaching to be learning, even if affecting and being affected are the same—provided that they are not the same in such a way that one account states the essence of each (as with cape and cloak), but in the way that the road from Thebes to Athens is the same as the road from Athens to Thebes, as was also stated previously?[110] For it is not the case that all the same affections belong to things that are the same in any way whatever, but only to those whose being is the same. Not even if teaching is the same as learning, however, would it be the case that to teach is the same as to learn, just as, not even if two places separated by an interval have one interval between them would it be the case that being separated by the interval from here to there is one and the same as being separated by the interval from there to here. But, speaking in general terms, neither teaching and learning nor affecting and being affected are in the strict sense the same, though what they belong to—the movement—is the same; for being the activation of this occurring in that and being the activation of that by this are distinct in account.

What movement is, then, has been stated, both universally and in particular cases; for it is not unclear how each of its forms will be defined; for alteration, for example, will be the actualization of the alterable, insofar as it is alterable. But to make it still better known: it is the actualization of what is capable of affecting or capable of being affected, insofar as it has that capacity, whether unconditionally or again in a particular case—for example, building or curing. And an account will be given in the same way concerning each of the other sorts of movement.

110. 202a18–20, b9.

3.4
The Unlimited

Since natural science is concerned with magnitudes, movement, and time, each of which must be either limited or unlimited, even if not everything is either limited or unlimited, for example, an affection or a point (for perhaps it is not necessary for any things of this sort to be either of these), it would be appropriate for the person who studies nature to get a theoretical grasp on the unlimited, whether it exists or not, and if it exists, what it is.

A sign that the theoretical investigation concerning the unlimited properly belongs to this science is that all those who are believed to have touched upon this sort of philosophy in a worthwhile way have produced an account of the unlimited, and all of them posit it as some sort of starting-point of the beings.

Some, such as the Pythagoreans and Plato, posit the unlimited as something existing in itself, not as a coincident of something else but as a substance. The difference is that the Pythagoreans say that it exists among the perceptibles (for they do not make number separable), and that what is outside the heaven is unlimited. Plato, by contrast, says that there is no body outside [the heaven], and that not even the Forms are there, because they are not in any place at all, but that the unlimited is present both in the perceptibles and in the Forms.

Also, the Pythagoreans identify the unlimited with the even (for this, they say, entrapped and limited by the odd, gives beings their unlimitedness; a sign of this, they think, is what happens with numbers; for when gnomons are arranged around the one and separately,[111] the form is always a distinct one in the latter case, and the same in the former). Plato, by contrast, has two unlimiteds, the great and the small.[112]

Those concerned with nature, on the other hand, all posit for the unlimited some other sort of nature, distinct from that of the so-called elements—for example, water, air, or what is intermediate between these. Among those who make the elements

111. The one is both odd and even (*Met.* 986ᵃ20). It is represented by ••, when even, and by • (separately) when odd. Enclose • with a gnomon (represented by lines). This gives Fig. A below. Now enclose •• with a gnomon. This gives Fig. B.

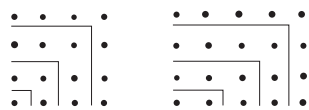

Fig. A Fig. B

In Fig. A, a series of squares (square or even numbers) is generated; in Fig. B, a series of rectangles (rectangular or odd numbers). The successive square or even numbers (2, 4, 6, 8, . . .) generated from • (the one taken as odd) are all the same in form (= n^2). The successive rectangular or odd numbers generated from •• (or the one taken as even) are all distinct in form, since the ratio n:n + 1 is different for all values of n.

112. 206ᵇ27–33.

limited [in number], however, none makes them unlimited [in quantity or extent], while those who make the elements unlimited [in number]—as Anaxagoras does from his homoeomeries, and Democritus from his universal seedbed of shapes—say that the unlimited is continuous by contact.

Anaxagoras says that any part is a mixture in the same way as the universe, because of seeing anything whatever coming to be from anything whatever; for it seems to be on the basis of that, that he also says that once upon a time all things were together (for example, this flesh and this bone), and likewise anything whatever, and therefore all things; and at the same time too; for there is a starting-point of the disaggregation not only in each thing, but also of all. For since what comes to be comes to be from a body of this sort; and since there is a coming to be of everything, although not at the same time; and since there must be some starting-point of the coming to be; and this starting-point is one, and of the sort that he calls "understanding"; and the understanding does its understanding and sets to work from some starting-point; it follows that all things were necessarily together at a certain time and started to be moved at a certain time. Democritus by contrast says that none of the primary things comes to be from another. Nonetheless, the common body is for him a starting-point of all, differing from part to part in magnitude and shape. **203^{b}1**

It is clear from these considerations, then, that the theoretical investigation [concerning the unlimited] is appropriate for natural scientists. It is reasonable too for them all to posit it as a starting-point; for they all think that it does not exist pointlessly and it cannot have any capacity except as a starting-point;[113] for everything is either a starting-point or from a starting-point. Of the unlimited, however, there is no starting-point; for, if there were, it would have a limit. Further, it is incapable both of coming to be and of passing away, as if it were a sort of starting-point; for what is coming to be must reach an end, and there is an end reached in every passing away. That is why, as we say, there is no starting-point of the unlimited, but it is rather the unlimited that seems to be a starting-point of the other things, and to encompass everything, and steer everything (as is said by those[114] who do not posit other causes beyond the unlimited, such as understanding or love), and to be divine; for in fact it is immortal and indestructible, as Anaximander says, and most of the natural scientists.

The conviction that something unlimited exists would seem to result mostly from investigating the following five things: time (for it is unlimited); the division of magnitudes (for mathematicians also make use of the unlimited); further if coming to be and passing away do not run out, it is only because what things coming to be are subtracted from is unlimited; further, what is limited always reaches its limit in relation to something, so that there can be no [ultimate] limit, if one thing must

113. Reading οὔτε γὰρ πάντες μάτην αὐτὸ οἴονται εἶναι.
114. Heraclitus B41 DK, Parmenides B12.3 DK.

always reach its limit in relation to another; and above all, and having most control on the outcome, is a point that produces a puzzle common to all thinkers: because number, mathematical magnitudes, and what is outside the heaven[115] do not in fact run out in thought, they all seem to be unlimited. (And if what is outside is unlimited, it seems that there is an unlimited body and unlimitedly many cosmoses; for why should these be here rather than there in a void?) So, if indeed the body with volume is somewhere, it is everywhere. At the same time, even if there is a void and an unlimited place, there must also be an unlimited body; for in the case of eternal things, there is no difference between being possible and being.

The theoretical investigation concerning the unlimited involves a puzzle; for in fact if we posit that it does not exist, many impossibilities result, as they do if we posit that it does exist. Further, [if it exists], in which of these two ways does it exist—as a substance or as an intrinsic coincident of some nature? Or does it exist in neither of these, yet nonetheless there is an unlimited, or things that are unlimited in number?

What above all belongs to the natural scientist, however, is to investigate whether there is a perceptible magnitude that is unlimited. The first thing, then, is to determine in how many ways things are said to be unlimited. We say so in one way, clearly, when the thing cannot be traversed because it is not in its nature to be traversed (in just the way that voiced sound is invisible); in another, when it admits only of unending traverse, or scarcely admits of traverse, or what—though by its nature it admits of traverse or limit—is not traversed or limited. Further, something may be unlimited with respect to addition, with respect to division, or both.

3.5
Pythagoreans and Platonists on the Unlimited

For the unlimited to be separable from the perceptibles, being itself something unlimited,[116] is not possible. For if the unlimited is neither a magnitude nor a plurality, but is itself a substance and not a coincident, it will be indivisible (for what is divisible is either a magnitude or a plurality); but if it is indivisible, it will not be unlimited except in the way in which voiced sound is invisible. It is not what is unlimited in this way, though, that is said to exist by those who assert that the unlimited exists, or that we are inquiring about, but what is so as untraversable. But if the unlimited is a coincident, it cannot—insofar as it is unlimited—be an element of beings, just as the invisible is not an element of speech, and yet voiced sound is invisible.

Further, how is it possible for some unlimited-itself to exist, if indeed both number and magnitude, of which the unlimited is a certain affection, cannot? For there

115. See 203^a7.

116. I.e., the unlimited cannot be the underlying subject for itself, in the way that the Platonic Form of X is the underlying subject for X (204^a17–18).

is still less necessity [for this in the case of the unlimited] than in the case of number and magnitude.

It is evident too that it is not possible for the unlimited to exist as actively so, and as a substance and a starting-point; for any part whatever of it that might be taken will be unlimited, if it is capable of having parts (for the being for the unlimited and the unlimited-itself were the same, if indeed the unlimited is a substance and not predicated of an underlying subject), so that either it is indivisible or it is divisible into unlimiteds. But for the same thing to be many unlimiteds is impossible (yet just as a part of air will be air, so too a part of the unlimited will be unlimited, if at any rate it is a substance and a starting-point). Therefore, the unlimited must be incapable of having parts and indivisible. But this is impossible for what is unlimited in actuality; for it must be a certain quantity. The unlimited, therefore, belongs [to beings] as a coincident. If that is so, however, it was stated[117] that it is not possible to call it a "starting-point," but rather what it is a coincident of: air or the even. So the view of those who say what the Pythagoreans say is absurd; for they both posit the unlimited as substance and divide it into parts.

But presumably this inquiry would be[118] universal: whether it is possible for there to be an unlimited present also in mathematical objects as well and in intelligible ones that have no magnitude. Our investigation, by contrast, concerns perceptibles and topics our methodical inquiry is concerned with: whether there is or is not present in them a body that is unlimited in increase.

If we investigate the issue logico-linguistically, it would seem from the following considerations that no such body can exist; for if the account of body is what is bounded by planes, there cannot be any unlimited body, whether intelligible or perceptible (nor can there be an unlimited number considered as separate and unlimited; for a number or what has a number is numerable, and so, if the numerable can be enumerated, it would also be possible to traverse the unlimited).

If, on the other hand, we get a theoretical grasp on the issue in a more natural scientific way, [the conclusion is further supported] by the following ones. An unlimited body cannot be either composite or simple [and yet must be one or the other]. It will not be composite, if the elements are limited in number. For there must be more than one element, and the contrary elements must always be equal, and no one of them can be unlimited; for however much one contrary in one body falls short in capacity of another (for example, suppose fire is limited and air is unlimited, and the capacity of a quantity of fire is any multiple whatever of that of an equal quantity of air, with the sole proviso that the multiple is some [finite] number), nonetheless it is evident that the unlimited body will overpower and destroy the limited one. But that each element should be unlimited is impossible; for a body is what has extension in

117. 204a14–17.
118. Reading ἂν εἴη.

all dimensions, while what is unlimited is what has unlimited extension, so that an unlimited body will be unlimitedly extended in all dimensions.

But then neither is it possible for an unlimited body to be one and simple, whether it exists, as some thinkers say, beyond the elements, and is what they generate these from, or simply exists.

For there are some who make this [body] unlimited, and not air or water, in order that the others may not be destroyed by the unlimitedness of air and water; for the elements have a contrariety with each other (for example, air is cold, water wet, fire hot), so if one of them were unlimited, the others would already have been destroyed. But as things stand, they say, there is a distinct thing, from which these come to be. It is impossible, however, for there to be such a thing, not because it is unlimited (for about this topic there is a common statement to be made that applies to all things alike, whether air, water, or anything whatever), but because there is no perceptible body of this sort beyond the so-called elements; for it is what they come to be from that all things are also dissolved into, so that the body in question would have to be here, alongside air, fire, earth, and water. But no such thing is observed.

Nor can fire or any other of the elements be unlimited. For, in general, and apart from whether any of the elements can be unlimited, it is impossible for the universe, even if it is limited, to be or come to be one of them, as Heraclitus says that at some time all things become fire. The same argument applies to the one that the natural scientists put beyond the elements; for everything changes from contrary to contrary—for example, from hot to cold.

{The general question of whether it is possible or impossible for there to be an unlimited perceptible body[119] must be investigated on the basis of the following considerations.}[120]

That it is, in general, impossible, then, for there to be an unlimited perceptible body is clear from the following. It is natural indeed for everything that is perceptible to be somewhere, and there is a certain place for each, and the same place for a part of it and for the whole—for example, for the totality of earth and a single clod, and for fire and a spark. So, if the unlimited perceptible body is uniform, it will be immovable or will always be moving. And yet this is impossible; for why down rather than up or than anywhere else? (I mean, for example, if there is a clod of earth, where will this move or be at rest? For the place of the body that is homogeneous with it is unlimited. Will the clod occupy the whole place, then? And, how? What, then, is its rest or movement, and where? Will it be at rest everywhere? In which case it will not move. Or be moving everywhere? In which case it will not rest.)

On the other hand, if the universe has dissimilar parts, their places will also be dissimilar, and, first, the body of the universe will not be one except by contact, and, second, the parts will be either limited or unlimited in form. But limited they

119. Retaining σῶμα ἄπειρον αἰσθητόν.

120. This sentence should perhaps be secluded.

cannot be; for then those of one sort will be unlimited and those of another will not (if the universe is unlimited)—for example, fire or water will be unlimited, but something like that will be destructive of its contraries, as was stated previously.[121] 25
But if the parts are unlimited and simple, their places are also unlimited, and 29
there will be an unlimited number of elements. But if this is impossible and the 30
places are limited, the universe must be limited too;[122] for it is impossible that place and body should not evenly match; for neither is place as a whole larger than the body can be (and, at the same time, the body would no longer be unlimited), nor is the body larger than the place; for otherwise either a void will exist or a body for which it is natural to be in no place whatever. And it was because of **205^b1**
this that none of the natural scientists made fire or earth the one unlimited body, 25
but either water or air or what is intermediate between them, because each of the former clearly has a definite place, while the others play a double game between up and down.[123]

Anaxagoras for his part speaks in a strange way about the unlimited being at rest; **205^b1**
for he says that the unlimited holds itself fixed, and that this is because it is within itself (for nothing else encompasses it), on the supposition that wherever anything is, it is there by its own nature. But this is not true, because a thing may be somewhere by force and not where it naturally is. So however true it may be that the 5
whole universe is not moved (for what holds itself fixed and is within itself must be immovable), it is still necessary to say why it is not in its nature to be moved. For it is not enough to make this statement and leave it at that; for anything else[124] could be not moving, although nothing in its nature prevents it from doing so. After all, the 10
earth does not spatially move either, and would not do so even if it were unlimited, provided it were still shut in by the center, but would remain at rest at the center,[125] not because there is nowhere it will be moved to, but because it is in its nature to do so. And yet one might say that it holds itself fixed. If, then, this is not the cause [of being at rest], even in the case of the earth, if it were unlimited, but the cause is that it has heaviness, and what has heaviness remains at rest at the center, and the earth is at 15
the center, likewise too the unlimited should remain at rest within itself due to some other cause, and not because it is unlimited and holds itself fixed.

At the same time, it is clear that any part whatever [of the unlimited] would have to remain at rest; for just as the unlimited remains at rest within itself, holding itself fixed, in the same way any part you take will remain at rest within itself; for the places 20
of the whole and of the part are uniform—for example, of the whole earth and of a clod, it is below, and of the totality of fire and a spark, it is above. So, if the place of

121. 204^b28. Retaining καθάπερ εἴρηται πρότερον.
122. Retaining πεπεράνθαι ἀναγκαῖον.
123. I.e., water and air have tendencies to move up (relative to earth) and down (relative to fire). The Bekker text of this paragraph is reorganized as indicated.
124. Reading ὁτιοῦν ἄλλο.
125. Retaining ἐπὶ τοῦ μέσου.

the unlimited is to be within itself, the place of a part will be the same. Therefore, it will remain at rest within itself.

In general, it is evident that it is impossible to say at the same time that there is an unlimited body and that there is some [proper] place for bodies, if every perceptible body has either heaviness or lightness, and, if it is heavy, has a spatial movement that is by nature toward the center, and, if it is light, upward; for this must be true of the unlimited as well. But it is impossible for all of it to have either of these affections or for a half to have one and a half the other; for how will you divide it? And how, of what is unlimited, can there be an above and a below, or an extreme and a center?

Further, every perceptible body is in a place, and the forms and differences of place are up and down, before and behind, and right and left. And these are not merely relative to us or to our position, but are also distinguished within the whole universe itself. But these cannot exist in the unlimited. Simply put, if there cannot be an unlimited place, and every body is in a place, there cannot be an unlimited body. Moreover, what is somewhere is in some place, and what is in a place is somewhere. If, then, the unlimited cannot even be a quantity (for, if it were, it would have to be some particular quantity, such as two or three cubits; for it is these that quantity signifies), in the same way that "in a place" signifies that a thing is somewhere, and this would be up, down, or in some other of the six directions, and each of these is a certain limit.

It is evident from these considerations, then, that there is no actively unlimited body.

3.6
The Way the Unlimited Exists

But if nothing is unconditionally unlimited, it is clear that many impossibilities result. For there will be a start and an end of time, magnitudes will not [always] be divisible into magnitudes, and number will not be unlimited. When the alternatives have been thus determined, and it seems that neither is possible, there is need of an arbitrator, and it is clear that in one way there is something unlimited and in another way there is not.

Things, as we know, are said to *be* either potentially or actually, and what is unlimited is so, on the one hand, by addition and, on the other hand, by division. It was stated,[126] however, that a magnitude is not actually unlimited, although by division it is unlimited; for it is not difficult to refute indivisible lines.[127] So it remains for what is unlimited to be so potentially. But, here, we must not take what is potentially in this way, that if this is potentially a statue, it will also be a statue, and suppose that there will be something actively unlimited.

126. 204ᵃ20–30.

127. *Met.* 992ᵃ19–22. See ††*On Indivisible Lines* 968ᵃ9–14.

Since, though, things are said to *be* in many ways, just as the day exists, and the games exist, because [during them] one thing is always coming to be after another, so it is too with the unlimited (for in the former cases as well there is a potentially and an actively; for the Olympic Games exist both in the sense of the competition's potentially occurring and of its actively occurring), it is clear that the unlimited exists in distinct ways, in the case of time, in the case of humans, and in the case of the division of magnitudes. For, in general, the unlimited exists in the following way, in virtue of one thing always being taken after another, and each thing taken is always limited, but is always, again and again, other. {Further, things are said to *be* in many ways, so that we must not take the unlimited to be a this something, such as a human being or a horse, but in the way that we say that something is a day or a competition, for which the being does not come about as a sort of substance, but always consists in a process of coming to be and passing away: a limited thing [at each stage], yet always one thing followed by another.}[128] Yes, but in magnitudes what was taken remains, while in the case of time and human beings what is taken is destroyed but in such a way that the supply does not give out. **206^b1**

The unlimited by addition is in a way the same as that by division; for, in what is limited, the unlimited by addition[129] occurs in an inverse way; for as it is seen being divided without limit, the same will appear to happen by addition to a definite part. For if in a limited magnitude one takes a definite part, and then were [always] to add another determined by the same ratio [of part to whole] (that is, not taking the same particular quantity of the whole), one will not traverse the limited magnitude. But if one increases the ratio, so that one always takes the same particular magnitude, one will traverse it, because every limited magnitude is exhausted by [taking in this way] any definite magnitude whatever.

In any other way, then, there is not anything unlimited, but in this way there is, potentially and by reduction, and in fact in the way[130] in which we say a day is and a competition is, and potentially in the way that matter is, and not intrinsically in the way that what is limited is.

The unlimited by addition too, then, exists potentially in this way, in the same sort of way, we say, as that by division; for although it will always be possible to take something external to it, it will not exceed every magnitude, in the way in which, in division, it exceeds every definite magnitude, and will always be smaller than it. So to exceed everything by addition is not possible even potentially, if indeed there is nothing that coincidentally is actually unlimited in the way that the natural scientists say that the body outside the cosmos, of which the substance is air or some other such thing, is unlimited. But if there cannot be in this way a perceptible body that is actually unlimited, it is evident that there cannot be one that is even potentially unlimited

128. This sentence should perhaps be secluded.
129. Reading τὸ κατὰ πρόσθεσιν.
130. Reading καὶ δὲ ἔστιν.

by addition, except, as was stated,[131] in an inverse way to being so by division. (It is because of this in fact that Plato posited two unlimiteds,[132] because there seems to be an excess and a going on without limit both in increase and in decrease. But though he posits two, he does not use them; for in numbers the unlimited in decrease is not present, because the unit is the smallest one, and the unlimited in increase is not present either, because he posits numbers only up to ten.[133])

It turns out, then, that the unlimited is the contrary of what people say it is. For it is not what nothing is outside of, but rather what something is always outside of, that **207[a]1** is unlimited. A sign of this is that people say that rings without a socket for a gemstone are unlimited, because it is always possible to take something that is outside. But they say this in virtue of a certain similarity, and not using the term in the strict sense; for this must hold and also the same thing must never be taken again. In the case of the circle, though, it does not happen that way, but only that the next thing is always a distinct one. Something is unlimited, then, of which—when we are taking quantities—it is always possible to take something that is outside. On the other hand, what nothing is outside of is complete and whole; for this is how we define what is whole, as that from which nothing is absent—for example, a whole human being or a whole box. And just as with the particular case, so too with what is whole in the strict sense: the whole is what nothing is outside of. But what there is something absent from and outside of is not an all, whatever it may be absent.[134] Whole and complete are either altogether the same or very close in nature.[135] Nothing is complete (*teleion*) that has no end (*telos*), and the end is a limit.

That is why Parmenides must be thought to have spoken better than Melissus; for Melissus says that the unlimited is a whole, Parmenides that the whole is limited, "equal in all directions from the middle."[136] For to connect the unlimited to the universe or whole is not a question of tying string to string, since it is from this that they get the dignity that they ascribe to the unlimited, that it encompasses all things and contains the universe within itself, because it has some similarity to the whole.

For the unlimited is the matter of the completeness of a magnitude,[137] and is what is potentially but not actually a whole, since it is divisible by reduction and by its inverse, addition; is a whole and limited not intrinsically but with regard to something else; and does not encompass but, insofar as it is unlimited, is encompassed. That is why the unlimited, insofar as it is such, is unknowable; for the matter has no form. So it is evident that the unlimited is found more in an account of a part than

in that of a whole; for the matter is a part of the whole, just as the bronze is of the bronze statue, since, if indeed the unlimited encompasses in the case of perceptibles, then, in the case of intelligible objects too, the great and the small should encompass the intelligible objects.[138] But it is absurd and impossible that the unknowable and indefinite should encompass and define.

3.7
The Various Sorts of Unlimited; Matter

It is in accord with reason too that there does not seem to be any unlimited by addition that is such as to exceed every magnitude, while there does seem to be one by division (for the unlimited, as the matter,[139] is what is encompassed and inside, while the form is what encompasses). It is also reasonable that while in number there **207^{b}1** is a limit in the direction of the least, though in the direction of the greater every magnitude is always exceeded, yet in the case of magnitudes, on the contrary, while any magnitude is exceeded in the direction of the less, in the direction of the greater there is no unlimited magnitude. The cause is that what is one is indivisible, whatever may be one (for example, a human being is one human being and not many), while number is a plurality of ones—a certain many of them. So there must be a stop at the indivisible (for "two" and "three" are paronymous names, and similarly with each of the other numbers). In the direction of the greater, however, it is always possible to think of [a greater number]; for the bisections of a magnitude are unlimited. So the unlimited exists potentially, not actively, although what is grasped always exceeds any definite plurality. But this number is not separable from the process of bisection,[140] and the unlimited does not stand fast but comes to be, just like time and the number of time.[141]

In the case of magnitudes, on the other hand, the contrary holds; for the continuous is divisible into unlimited parts, while there is no unlimited in the direction of the greater. For whatever size a [perceptible] magnitude can be potentially, it can also be actively. So, since no perceptible magnitude is unlimited, it is impossible to exceed every definite magnitude—for then there would be something greater than the heaven.

The unlimited is not the same thing in magnitude, in movement, and in time, as if it were some one nature. Rather, the posterior among these is said to be unlimited with reference to the prior—as, for example, a movement is said to be unlimited in

138. Yet Plato posits the great and the small as the material element, and the one as the formal element, from which the Forms on the one hand and the perceptibles on the other are generated. See *Met.* $987^{b}20–21$, $988^{a}10–14$.
139. Reading ὡς ἡ ὕλη.
140. Reading τῆς διχοτομίας.
141. $206^{b}1–2$.

virtue of the fact that the magnitude, the vehicle of movement, is altered or increased, and the time because of the movement. For now let us make use of these notions, but later[142] we will state what each of them is and why every magnitude is divisible into magnitudes.

But our account does not deprive the mathematicians of their theoretical investigation either, in thus doing away with the existence of an unlimited that is actively untraversable in the direction of increase; for even as things stand they do not need the unlimited (for they make no use of it), but only that there should be a limited line of whatever length they wish. But another magnitude of any size you like can be divided in the same ratio as the greatest one can, so that, as regards proof at least, it makes no difference to them that its being among the magnitudes that actually exist is not necessary.[143]

Since there is a fourfold division of causes, it is evident that the unlimited is a cause as matter, and that the being for it is privation, while the intrinsically underlying subject is what is continuous and perceptible. All the other thinkers as well manifestly make use of the unlimited as matter. That is why it is absurd to make it what encompasses and not what is encompassed.

3.8
Refutation of Arguments for the Actually Unlimited

It remains to go through the arguments[144] that seem to support the view that the unlimited exists not only potentially but as something definite; for some of them are not necessities, while others admit of other true replies.[145]

In order that coming to be should not run out, it is not necessary for there to be a perceptible body that is actively unlimited; for it is possible for the passing away of one thing to be the coming to be of another, the universe being limited.

Further, making contact and being limited are distinct. For the former is a relative, that is, it is making contact with something (for everything that makes contact makes contact with something), and is a coincident of some limited things. But what is limited is not a relative. Nor is it possible for any random thing to make contact with any random thing.

It is absurd to put your trust in thought; for then the excess and deficiency are not in the thing but in thought. For one might think of each of us as being many times as large as himself, increasing our size without limit; but it is not because of this, that

142. 5.1–2, 4.

145. I.e., some objections will be to the deductive validity of the arguments to be examined, others to their soundness, or the truth of their premises.

someone thinks it is so, that anyone exceeds the size of his city (*astu*)[146] or the size that we have, but because it is the case; that someone thought it is so is coincidental.

Time, movement, and thought are unlimited things, in that what is taken does not remain.

Magnitude is not unlimited, either by way of reduction or by way of increase, in thought.

In what way the unlimited exists, then, in what way it does not exist, and what it is has now been stated.

BOOK 4

4.1
The Existence of Place

It is likewise necessary for a natural scientist to know about place too, just as about the unlimited, whether it exists or not, what way it exists, and what it is. For everyone supposes that the beings are somewhere (for a non-being is nowhere; for where is a goat-stag or a sphinx?), and movement in the most common and strictest sense, which we call "spatial movement," is movement with respect to place.

The question of what exactly place is, however, involves many puzzles; for it does not appear to be the same thing to those who get a theoretical grasp on it based on all the facts [as to those who do not]. Further, we have nothing from previous thinkers either by way of going through the puzzles about it or of making us puzzle-free. **$208^{b}1$**

That place exists seems to be clear from replacement; for where there is now water, there, when the water has gone out as from a vessel, air is in turn present. Then[147] some other bodies occupy this same place. The latter, then, seems to be something distinct from all the things that come to be in it and change; for what air is in now, water was previously in, so that it is clear that the place, that is, the space into which they entered and from which they left, was something distinct from either of them.

Further, the spatial movements of the simple natural bodies—for example, fire, earth, and the like—make it clear not only that place is something but also that it has a certain capacity. For each spatially moves to its own place if it is not prevented, fire up above, earth down below. These are the parts and forms of place—up and down and the rest of the six directions. And these—up and down, right and left—are not just relative to us; for in relation to us they are not always the same, but come to be in accord with our position, depending on how we are turned. That is why left and right are often the same, as are up and down, and before and behind. In nature, by contrast, each is distinct and separate. For up above is not some random thing, but

146. Retaining τοῦ ἄστεός.
147. Reading ὅτε.

where fire and what is light spatially move to. Similarly, down below is not some random thing, but where what has heaviness and what is earthen spatially move to, as differing not in position alone but in capacity as well. (Mathematical objects also make this clear; for though they are not in a place, nonetheless they have a right and left in accord with their position relative to us, in the sense in which these are said of things merely because of their position, and not in the sense of having either of them by nature.) Further, those who say that a void exists say that place does; for a void would be a place lacking body.

It is through these considerations, then, that one might take place to be something beyond bodies, and all perceptible bodies to be in a place. And even Hesiod might seem to be speaking correctly in making chaos come first. At any rate, he says, "Of all things the very first that came to be was chaos, and then broad-breasted earth,"[148] on the supposition that there needs first to be a space for the beings, because he believed, as most people do, that everything is somewhere and in a place. If this is so, however, then the capacity of place must be a wonderful one and prior to all things; for that without which nothing else can exist, while it can exist without the others, must be first; for place is not destroyed when the things in it pass away.

Nonetheless, there is still a puzzle, if place exists, as to what it is, whether some sort of volume for body, or some other sort of nature; for we must first inquire about what its kind is.

A place, then, has three dimensions, length, breadth, and depth, by which every body is bounded. Yet it is impossible for place to be a body; for then there would be two bodies in the same place.

Further, if indeed a body has a place and a space, it is clear that the surface and the rest of a body's limits do as well; for the same argument will apply; for where previously the surfaces of the water were, there those of the air in turn will be. But we have no way to distinguish between a point and the place of a point. So, if the place of a point is not distinct from it, neither will that of any of the others be, and nor will place be something beyond each of these.

What exactly, then, are we to suppose place to be? For if it has a nature of the sort that was mentioned, it cannot be an element or composed of elements, whether of corporeal or of incorporeal ones; for while it has magnitude, it has no body. The elements of perceptible bodies,[149] by contrast, are bodies, while from intelligible objects no magnitude comes to be.

Further, of what in beings could one suppose place to be the cause? For none of the four causes is present in it; for it is neither a cause as matter for the beings (for nothing is composed of it), nor as form and account of things, nor as end, nor does it cause the beings to move.

148. *Theogony* 116–117.

149. Reading τῶν αἰσθητῶν σωμάτων.

Further, if it is itself one of the beings, it will be somewhere. For Zeno's puzzle demands some argument [in response];[150] for if every being is in a place, it is clear that there will be a place of place too, and so on without limit.

Further, just as every body is in a place, so too in every place there is a body, so what are we to say about things that increase in size? For from what has been said it must be that their place increases along with them, if each of their places is neither smaller nor larger than they are.

Due to these things, then, it is necessary to puzzle over not only what place is, but also whether it exists.

4.2
Is Place Matter or Form?

Since some things are said to be something intrinsically, others in virtue of another thing, and place may be either the common place in which all bodies are, or the special one, which a given body is in first (I mean, for example, that you are now in the heaven because you are in the air and it is in the heaven, and you are in the air because you are on the earth, and similarly you are on it because you are in this place, which encompasses nothing more than you), then, if place is the first thing encompassing each body, it would be a certain limit. So place would seem to be the form and the shape of each body, by which the magnitude, and the matter of the magnitude, are bounded; for this is what the limit of each is. If one investigates it in this way, then, place is the form of each thing. But insofar as place seems to be the extended space of the magnitude, it is the matter; for this is distinct from the magnitude: it is what is encompassed and bounded by the form, as by a surface, that is, a limit. And this is the sort of thing that the matter and the indefinite are; for when the limit and the affections of a sphere are subtracted, nothing is left beyond the matter.

That is why Plato too says in the *Timaeus*[151] that matter and space are the same thing; for what makes participation possible and space are one and the same. Although he spoke of what makes participation possible in another way in the so-called unwritten doctrines, nonetheless he still declared that place and space were the same thing. In fact, while everyone says that place is something, he alone tried to say what it is.

It makes perfect sense, then, that when we investigate the question on the basis of these considerations it seems difficult to know what place is, if indeed it is one or the other of these two things, either matter or form. In any case, not only do these in fact involve theoretical knowledge of the highest sort,[152] but it is not easy to know them in separation from each other.

150. $212^{b}27–29$.
151. 51a–b with 52a8, b4.
152. *Met.* $1003^{a}26$.

But surely it is not difficult to see at least that it is impossible for place to be either of them. For the form and the matter are not separate from the thing, while the place admits of being so; for what air was in, water in turn comes to be in, as we said,[153] when the water and the air replace each other, and similarly when other bodies do. So the place of each thing is neither a part nor a state of it, but is separable from it. For in fact place seems to be something like a vessel (for a vessel is a transportable place). The vessel, though, is nothing belonging to the thing. Insofar, then, as it is separable from the thing, place is not the form; and insofar as it encompasses, it is distinct from the matter. Also, what is somewhere always seems both itself to be something and to have some distinct thing outside it. (Plato must tell us, then, if we may make a parenthetical comment, why the Forms and the numbers are not in a place, if indeed place is what makes participation possible, whether what makes participation possible is the great and the small or matter, as he wrote in the *Timaeus*.[154])

Further, how could a thing spatially move to its own place, if the place is the matter or the form? For it is impossible for what there is no movement of and no up and down to be place. So place must be sought among things that are of this sort. And if place is in the thing itself, as it must be if indeed it is either shape or matter, place will be in a place; for both the form and the indefinite change and are moved at the same time as the thing, and are not always in the same place, but are just where the thing is. So there will be a place of the place.

Further, when water comes to be from air, the place has been destroyed, for the body that comes to be is not in the same place. Of what sort, then, is this passing away?

On the basis of these considerations, then, that it is necessary for place to be something, and, again on their basis, that puzzles might be raised as to what its substance is, has now been stated.

4.3
Can a Thing Be in Itself or a Place in a Place?

We must next get a grasp on how many ways one thing is said to be *in* another. One way, then, is as the finger is in the hand, and, in general, as the part in the whole. Another, as the whole is in the parts; for the whole does not exist beyond the parts. Another way, as human is in animal, and, in general, form in kind. Another, as the kind is in the form, and, in general, the part of the form in the account. Further, as health is in hot and cold things, and, in general, the form in the matter. Further, as the affairs of the Greeks are in the king,[155] meaning, in general, in the first thing capable of causing movement. Further,

153. 208ᵇ1–8.
154. An apparent misunderstanding of 51a–b.
155. In the sense of being in his hands.

as in the good, and, in general, as in the end (that is, the for-the-sake-of-which). In the strictest way of all, as a thing is in a vessel, and, in general, in a place.

One might also raise a puzzle as to whether a thing can possibly be in itself, or nothing can, but rather everything is either nowhere or in something else. And this in two ways, either intrinsically or in virtue of something else. For when what is in something and what it is in are parts of the whole, the whole will be said to be in itself; for things are also said to be what they are with reference to their parts—for example, a human being is said to be pale, because his surface is pale, or to know science because his rationally calculative part does. The jar, then, will not be in itself, nor will the wine, but the jar of wine will be; for the thing that is in something and the thing it is in are both parts of the same thing.

In this way, then, it is possible for a thing to be in itself, but in the primary way it is not possible. For example, the pale is in a body (for the surface is in a body), and the scientific knowledge in a soul, and [the human being] is called what it is with reference to these, which are parts, at any rate when considered as in a human being (but the jar and the wine are not parts when separate, but are when together; that is why, when they are parts, the thing will be in itself)—for example, the pale is in a human being because it is in a body, and it is in a body because it is in a surface, but it is not any longer in a surface in virtue of something else. And these things—the surface and the pale—are at least distinct in form, and each has a distinct nature and capacity. **210^b1**

When we investigate inductively, then, we do not see anything being in itself in any of the ways distinguished, and when we do so by argument it is clear that it is impossible; for each of the two things would have to be both of them—for example, the jar would have to be both the vessel and the wine, and the wine both the wine and the jar, if indeed it is possible for a thing to be in itself. So however much they may be in each other, the jar will still be receptive of the wine not insofar as the jar is itself wine but insofar as it is a jar, and the wine will be in the jar not insofar as it is itself a jar but insofar as it is wine. It is clear, then, that with respect to their being they are distinct; for the account of the thing something is in is distinct from the account of the thing that is in it. Moreover, it is not possible coincidentally either; for then two things will be in the same [place] at the same time; for the jar will be in itself, if a thing whose nature is receptive can be in itself, and further, what it is receptive of—for example, if wine, then wine—will be in it.

It is clear, then, that it is impossible for something to be in itself in the primary way.

Zeno's puzzle, that if place is something, it will be in something, is not difficult to resolve; for there is nothing to prevent the first place from being in something else, although not in the way in which the thing is in that place, but rather in the way in which health is in hot things as a state, or in which the hot is in the body as an affection. So it is not necessary to go on without limit.

In the other case, it is evident that since the vessel is nothing belonging to what is in it (for in the primary way what [something is in] and what is in it are distinct),

place will not be either the matter or the form, but something else. For these—both
30 the matter and the shape—are something belonging to what is in a place.

Let this, then, serve as going through the puzzles.

4.4
What Place Is

What exactly place is should become evident from what follows. Let us assume about it, then, all the things that truly seem to belong intrinsically to it. We think, then, that place is the first thing encompassing that of which it is the place, and is nothing
211ᵃ1 belonging to the thing; further, that the primary place is neither less nor greater than the thing; further, that it can be left behind by the thing and is separable from it; in addition, that every place has an up and down; that each body should by nature
5 spatially move to and remain in its proper place, and does this either upward or downward.[156] With these as hypotheses, then, we must get a theoretical grasp on the rest. And we must try to make our investigation in such a way that the what-it-is is given an account of, so that the puzzles are resolved, the things that are believed to belong to place will in fact belong to it, and further, so that the cause of the difficulty
10 and of the puzzles concerning it will be evident; for this is the best way of proving each thing.

First, then, it must be understood that place would not be a subject of inquiry, if movement with respect to place did not exist; for it is most of all because of this that we think that even the heaven is in a place, because it is always in movement. Of movement with respect to place, one sort is spatial movement, the other increase and
15 decrease; for in increase and decrease too something changes, and what previously was there changes its place in turn into a larger or smaller one. And what is moved actively is so either intrinsically or coincidentally. And what is moved coincidentally is either what admits intrinsically of being moved—for example, the parts of the
20 body and the nail in the ship; or what do not admit of it, but instead are always moved coincidentally—for example, paleness and scientific knowledge; for these change their place in this way: because what they are present in changes its place.

We say that something is in the heaven as being in a place, because it is in the air,
25 and the air is in the heaven. And it is in the air, though not in all of it. But, because the innermost extremity of the air encompasses the thing, we say that it is in the air (for if all the air were its place, the place of a given thing would not be equal to the thing; but it certainly seems to be equal, and this primary place in which it is, is of this sort). When, then, what encompasses a thing is not divided from it but contin-
30 uous with it, the latter is said to be in the former not as in a place, but as the part is in the whole. On the other hand, when what encompasses a thing is divided from it

156. For the sake of simplicity the other four directions and the other proper places are ignored.

and makes contact with it, the latter is in its first [place] in the [innermost] extremity of the former, which is neither a part of what is in it, nor greater than its extended space, but equal to it; for the extremities of things that are making contact are in the same place. And if it is continuous with what encompasses it, it is moved not in it but with it; while if it is divided, it is moved in it, and whether what encompasses it is moved or not makes no difference.

{Further, when it is not divided from what encompasses it, it is said to be in it as a part of a whole, as the pupil in the eye, or the hand in the body, while when it is divided, as the water in the vessel or the wine in the jar; for the hand is moved with the body, while the water is moved in the vessel.}[157] **211^{b}1**

It is already evident from these considerations what place is. For there are pretty much four things of which place must be one: shape, matter, a certain extended space (the one in between the extremities), or the extremities, if there is no extended space beyond the magnitude of the body that comes to be in it. But it is evident that it cannot possibly be three of these.

It is because it encompasses something that place seems to be shape; for the extremities of what encompasses something and of what it encompasses are in the same place. But though they are both limits, they are not limits of the same thing. On the contrary, the form is that of the thing, while the place is that of the encompassing body.

Because the thing encompassed and divided from what encompasses it often changes, however, while the latter remains unchanged, like water poured from a vessel, what is in between seems to be a certain extended space, on the supposition that the latter is something beyond the body that changes its place. But that is not so. Instead, a random body, among those naturally capable of changing place and of making contact with others, enters it. And if there were a certain extended space that naturally remained unchanged,[158] then there would be an unlimited number of places in the same place (for when the water and the air change places, all the parts will do the same thing in the whole as all the water in the vessel does). At the same time the place too will be undergoing change, so that there will be another place of the place, and many places will be together. But the place of the part, in which it moves when the whole vessel changes places, is not a distinct one; rather, it is the same one; for it is in the place in which they are that the air and the water (or the parts of the water) change places. But this does not hold true regarding the place in which they come to be, which is part of the place that is the place of the whole heaven.[159]

157. Secluded as a dittograph of 211^{a}29–36.

158. Reading εἰ δ' ἦν τι διάστημα τὸ πεφυκὸς καὶ μένον, ἐν τῷ αὐτῷ τόπῳ.

159. Suppose that P_1 is a place that is part of P, which is the place inside PV_1, which is the proper place of a vessel V. When V moves from PV_1 to another proper place PV_2, the place within which P_1 moves does not change, but continues to be P. If P_1 were an intrinsic being, however, with a proper place of its own, this would not be true. Instead P_1 would move from a proper place inside PV_1 to one inside PV_2.

The matter too might seem to be place, if at any rate one investigated something at rest and not separated but continuous. For just as, if a thing undergoes alteration, there is something that now is pale but once was dark, or now is hard but once was soft, which is why we say that matter is something, so too place seems to exist because of a phenomenon of this sort—except that in the former case it is because what was air is now water, while place is thought to exist because where there was air, there is now water. But the matter, as was said in the previous discussions,[160] is neither separable from the thing nor encompasses it, while place is or does both.

Therefore, if place is none of the three, neither the form, the matter, nor some extended space which is always there, distinct from and beyond the extension of the thing that changes its place, it must be that place is the remaining one of the four, the limit of the encompassing body at which it is in contact with what is encompassed. (By "what is encompassed" I mean a body that can be moved by way of spatial movement.)

Place seems to be something important and difficult to grasp, both because the matter and the form appear alongside it and because the change of place of the moving body occurs within an encompassing body that is at rest; for it seems possible that there is an extended space in between that is something distinct from the magnitudes that move. And air contributes something to the belief by seeming to be incorporeal; for it is not only the limits of the vessel that appear to be a place, but also what is in between them, which is regarded as being void. And just as a vessel is a place that can be carried around, so a place is a vessel that cannot be moved. That is why, when something moves and changes inside something that is in movement (for example, a boat in a river), the thing that encompasses it serves more as a vessel than a place. But a place is meant to be immovable; that is why it is more the whole river that is the place, because as a whole it is immovable.[161] So the first immovable limit of what encompasses the thing—this is [its] place.

And this why the center of the heaven and the extreme limit (relative to us) of its circular spatial movement seem to everyone to be most of all up and down in the strict sense, because the center always remains at rest, and the ultimate limit of the circle remains as it was. So, since what is light is what by nature spatially moves upward, and what is heavy is what by nature spatially moves downward, the encompassing limit in the direction of the center is down, as is the center itself, while the one in the direction of the extremity is up, as is the extremity itself. And it is because of this that place is thought to be a sort of surface, and like a vessel and something that encompasses a thing. Further, place is together with the thing; for the limits are together with what is limited.

160. 209^b23, 207^a35.

161. X is moving inside a boat Y that is moving on river Z. In relation to X, Y serves more as a vessel than a place, since Y is moving, and places cannot move. In what place, then, is X moving? It is Z, which regarded as such is, like all places, immovable.

4.5
Puzzles about Place Solved

A body, then, that has some outside body encompassing it is in a place, while one that hasn't is not. That is why, even if something of the latter sort were to be water, its parts will be moved (for they encompass each other), while the universe will in one way move and in another not. For considered as a whole it does not at one and the same time change its place, though it will be moved in a circle—for the whole is the place of the parts—and some of these are moved not upward and downward but in a circle, others upward and downward, namely, those that admit of condensation and rarefaction.

As was said,[162] though, some things are potentially in a place, others actively. That is why, when a uniform thing is continuous, the parts are potentially in a place, while when they are separated and yet in contact, as in a heap, they are actively so.

Also, some things are intrinsically in a place (for example, every body that is movable either by way of spatial movement or by way of increase is intrinsically somewhere; but the heaven, as was said,[163] is not anywhere as a whole, nor in any place, if at any rate no body encompasses it; yet as it is moved,[164] it is in fact a place for its parts; for they are in contact with each other).

Other things, by contrast, are coincidentally in a place—for example, the soul and the heaven; for the parts [of the heaven] are all in a way in a place, as one encompasses another on the circle. That is why what is up above is moved in a circle, though the universe is not anywhere. For what is somewhere is both itself something, and further, there must be something else beyond it that it is in—what encompasses it. But beyond the universe and the whole there is nothing that is outside the universe, and that is why everything is within the universe; for the heaven, presumably, is the universe. Yet their place is not the heaven, but a part of the heaven, which is an extreme one and one that makes contact with the movable body. That is why the earth is in the water, the water in the air, the air in the ether, and the ether in the heaven, while the heaven is no longer in anything else.

It is evident from these considerations that all the puzzles[165] will also be resolved if we speak of place in the foregoing way. For it is not necessary for the place to increase along with the thing in it, or for a point to have a place, or for two bodies to be in the same place, or for place to be some corporeal extension (for what is between [the limits] of the place is whatever random body it may be, not the extension characteristic of a body). Also, place too is somewhere, although not as in a place, but in the

163. $212^{a}32$.
164. Reading ἐφ' ὃ.
165. Stated at $209^{a}2$–30.

way that a limit is in what is limited. For not every being is in a place, but [only] movable body.

Also, it is reasonable, then, that each [movable body] moves to its own place (for what is adjacent to something and not by force in contact with it is of the same kind as it; and if they are naturally unified, they cannot affect each other,[166] while if they are [only] in contact, one is affected and the other affects it). Also, that each should by nature remain in its proper place is not unreasonable; for the part does too—what is in a place is like a detached part in relation to the whole, as when one causes movement in a part of water or of air. It is in this way too that air is related to water; for the one is, as it were, matter, the other form—water being the matter for air, while air is, as it were, a sort of activation of water; for water is potentially air, while air is potentially water in another way. (We must, however, make determinations about these topics later,[167] although it is necessary, because the occasion calls for it, to say what we have said; what has now been stated in a non-perspicuous way will then be stated in a more perspicuous one.) If, then, the same thing is matter and actuality (in fact, water is both, but one potentially and the other actually), it will be somehow as a part is related to the whole. That is why these things have contact, and are naturally unified, when they both become actively one.

Also, as regard place, both that it is and what it is, has now been stated.

4.6
Views about the Void

In the same way, we must suppose that it belongs to the natural scientist to get a theoretical grasp on the void as well, as to whether it exists or not, in what way it exists, and what it is, just as in the case of place; for in fact conviction and lack of conviction are much the same in the two cases, because of what people assume; for those who speak of the void as existing suppose it to be, as it were, a sort of place or vessel, which seems to be a plenum when it contains the volume it is capable of receiving, and void when it lacks it, on the supposition that void, plenum, and place are the same thing, although the being for them is not the same.

We must start the investigation, however, by grasping what is said by those who assert that a void exists, then what is said by those who deny that it does, and third the common beliefs about these issues.

Those, then, who try to prove that a void does not exist in fact refute not what people mean by "void," but what they themselves say[168] in error about it, as Anaxagoras does and those who try to refute it in this way. For they prove that air is

166. *Met.* 1046ᵃ22–29.
167. *GC* 1.3, *Mete.* 4.1–2.
168. Rejecting the addition of ὃ.

something, by twisting wineskins and proving how strong the air is, and by trapping it in clepsydras.

But what people mean by "void" is an extended space in which there is no perceptible body. They, however, thinking that all being consists of bodies, say that what there is nothing at all in is void, because what is full of air is void. But it is not this that needs to be proved, that air is something, but that there is no extended space, either separable or actively existing, that is distinct from bodies, and that divides the totality of body so that it is not continuous (as Democritus, Leucippus, and many other of the natural scientists say), or is perhaps even outside the totality of body, which is continuous. **213b1**

These thinkers, then, do not meet the problem head on, but rather those who say that a void does exist. And they say, for one thing, that there would be no movement with respect to place (that is, spatial movement and increase); for [they say that] there would not seem to be movement, if there were no void; for a plenum cannot be receptive of anything. If it were to be receptive of something, and there were two things in the same place, it would be possible for any number of bodies whatever to be together; for one cannot say what difference in number would cause what is stated not to hold. But if this is possible, then the smallest thing will be receptive of the greatest; for a great thing is many small ones. So, if it is possible that many equal things should be in the same place, it is also possible that many unequal things should be. (Melissus even proves on the basis of these considerations that the universe is immovable; for if it is to be moved, there must (he says) be a void, but a void is not among the beings.) One way, then, in which they prove that there is a void is on the basis of these considerations.

Another is from the fact that some things are seen to contract and be compressed—for example, they even say that wine-jars will be receptive of the wine along with the wineskins, on the supposition that the condensed body contracts into the voids within itself.[169]

Further, increase too seems to all of them to occur by means of a void; for nourishment is a body, and it is impossible for two bodies to be together [in exactly the same place].

They also produce as evidence the [vessel] that surrounds ashes, which is receptive of as much water as the empty vessel.[170]

The Pythagoreans too said that a void exists, and that it enters the heaven itself from the unlimited breath, as the heaven is also inhaling the void that distinguishes the natures of things, since it is what separates and distinguishes the successive things in the series. This happens first in the case of the numbers; for the void distinguishes their nature.

169. Wine consists of atoms and voids. When it is poured from wineskins into wine-jars, it is compacted by the greater mass of wine in the wine-jar, so that previous voids are now filled with atoms.

170. Because there are many empty spaces in ash.

The grounds, then, on which people say that there is, or that there is not, a void are pretty much these and this many.

4.7
What a Void Is; Refutation of Arguments for the Existence of a Void

As a step toward determining which of these two alternatives holds, we need to grasp
30 what the name void signifies. A void, then, seems to be a place in which there is nothing. The cause of this is that people think that to be is to be a body, that every body is in a place, and that a void is a place in which there is no body, so that if there is no body somewhere, then there is nothing there. Moreover, they think that every body
214a1 is tangible, and that whatever has heaviness or lightness is of this sort. It follows by deduction, then, that a void is what there is nothing heavy or light in. These things, then, as we said previously, follow by deduction. It is absurd, then, to ask whether a point is a void; for a void must be a place within which there is an extended space
5 for a tangible body.

But, in any case, it appears that something is said to be a void in one way when it is not filled with a body that is perceptible by touch. (What is perceptible by touch is whatever has heaviness and[171] lightness. That is why someone might raise a puzzle as to what people would say if the extended space contained a color or a sound—is
10 it a void or not? Or is it clear that [they would respond that] if it were receptive of tangible body, it would be a void, and if not, not?) In another way, something is said to be a void when there is not a this something in it, nor a corporeal substance. That is why some people say that a void is the matter of a body (and they say that the place too is this same thing), but they do not speak correctly; for the matter is not
15 separable from the things, but they are inquiring about the void on the supposition that it is separable.

Since we have discussed place,[172] and void must, if it exists, be place lacking body, and it was stated in what way place exists and in what way it does not, it is thus evident that a void does not exist, whether separated or non-separated. For a void is
20 meant to be not a body but rather an extended space for a body. That is also why a void too seems to be something, because place is, and because of the same considerations. For certainly movement with respect to place comes to the aid both of those who say that a place is something beyond bodies that come to occupy it and of those who say the same about a void. They think that a void is a cause of movement in the sense of being what movement takes place in, and this would be the sort of thing that
25 some people say place is.

171. Reading καὶ.
172. 4.1–5.

But there is no necessity whatever, if movement exists, for there to be a void. In general, as regards all movement, it is not necessary in the least, due to something that Melissus also overlooked, that it is possible for a plenum to undergo alteration. But then it is not necessary for movement with respect to place either; for it is possible for things to make way for each other all at once, even though there is no separated extended space beyond the moving bodies. And this is clear in the rotations of continuous things, just as it is too in those of liquids.

Also, it is possible for things to be condensed not into a void but through the squeezing out of what is contained in them (for example, the air inside when water is condensed), and for it to increase not only by the entry of something else, but also by undergoing alteration—for example, when air comes to be from water.[173]

In general, both the argument about increase and about the water poured on the ashes are self-impeding. For either not any and every part increases, or it does so not by [the addition of] a body, or it is possible for two bodies to be in the same place, or it is necessary for the whole body to be a void, if it increases at every point and increases by means of a void. They are requiring that we resolve a puzzle common to both sides,[174] then, not proving that a void exists. The same argument applies to the ashes as well.

It is evident, then, that it is easy to resolve the puzzles on the basis of which they prove that a void exists.

4.8
No Void Separate from Bodies, or Occupied by a Body

Let us go back to saying that no separated void exists in the way in which some people say it does. For if each of the simple bodies has by nature a certain spatial movement (for example, fire upward and earth downward, that is, toward the center), it is clear that a void would not be the cause of their spatial movement. Of what, then, will a void be a cause? For it is thought to be a cause of movement with respect to place, but is not a cause of this.

Further, if when a void exists there is something like a place lacking a body, where will a body placed in it spatially move to? For it certainly cannot be to all of it. The same argument applies as to those who think that place is something separated that things spatially move to; for how will what is placed in it spatially move? Or will it remain at rest? And it makes perfect sense that the same argument fits both in the cases of the up and the down and also in the case of a void; for those who say that a void exists make it a place.

173. *GC* $321^{a}9$–29.
174. To account for the phenomenon of increase in size (*GC* $321^{a}2$–$322^{a}33$).

Also, in what way will something be in either a [separated] place or a void? For it does not result [as the defenders of the void suppose] when some whole is put in a separated place or in some body[175] that remains; for a part of it, if not put in separately, will not be in a place but in the whole body.[176] Further, if a [separated] place does not exist, neither will a void.

As for those who say that it is necessary for a void to exist if indeed there is to be movement, what results turns out to be the contrary, if one investigates the issue, that it is not possible for anything at all to move if a void does exist.

For just as some people say that the earth is at rest because of the sameness [of what surrounds it], so in a void too it is necessary [for the bodies] to be at rest; for there is nowhere for them to move to more or less [than to any other direction]; for a void, insofar as it is a void, admits of no differentiation.

215a1 Again, every movement is either by force or in accord with nature. And if there is the sort that is by force, there must also be the sort that is in accord with nature (for the sort that is by force is contrary to nature, and the sort that is contrary to nature is posterior to the sort that is in accord with nature). So, if each of the natural bodies does not have a natural movement, they will not have any of the other movements either. But how can there be movement that is by nature, if there is no differentiation throughout the void and the unlimited? For insofar as it is unlimited, there will be no up, down, or center, and, insofar as it is a void, up will be no different from down (for just as there is no differentiation of non-being, so neither is there any of the void; for a void seems to be a non-being and a privation). But spatial movement that is by nature is differentiated, so that there will be differences by nature. Either, then, nothing whatever has any spatial movement that is by nature, or, if there is spatial movement, there is no void.

Further, as things stand, things that are thrown move when what propelled them is not in contact with them—whether because of reciprocal replacement, as some people say,[177] or because the air that has been propelled propels them with a movement that is faster than the spatial movement by which what is propelled spatially moves to its proper place. But in a void none of these things holds, nor can anything be moved except in the way that what is carried is moved.

Further, none of these thinkers would be able to say why something that has been caused to move will stop somewhere; for why should it do so here rather than there? So a thing must either be at rest or must spatially move on without limit, unless something stronger impedes it.

175. Reading σώματι.

176. The idea seems to be this. A separated place P_s is like a body B. So suppose B occupies P as some whole W is supposed to occupy a part P_x of P_s. Unless a part of B is put into it separately, it will not be in a part of P, but in P as a whole (that is, in B, which occupies P). Therefore, by the same argument, W will not be in P_x.

177. E.g., Plato, *Timaeus* 59a.

Further, as things stand something is thought to spatially move in a void because the void yields to it, but in a void such yielding is everywhere alike, so that it will move in every way.

Further, the truth of what is being said is evident from the following considerations. For we see that the same weight or body spatially moves faster due to two causes, either because of a difference in the medium through which it spatially moves (for example, through water or earth, or through water or air) or because what spatially moves, other things being equal, is different due to the excess of heaviness or lightness.

The medium through which it spatially moves is a cause, in that it impedes the thing, most of all if its spatial movement is in the opposite direction, and next most if it remains unchanged. And more so a medium that is not easily divided, and a denser medium is of this sort. A, then, will spatially move through B in time C, and through D, which is more fine-grained, in time E, these being proportional to [the density of] the impeding body, provided the length of B is equal to that of D. For example, let B be water and D air, then to the degree that air is more fine-grained and less corporeal than water, to that degree A will spatially move through D faster than through B. Let speed stand in the same ratio to speed, then, as air differs in density from water, so that if air is twice as fine-grained, B will spatially move through in twice as much time as it takes to move through D, and the time C will be twice the time E. It will always be, then, that to the degree to which the medium spatially moved through is more incorporeal, less impeding, and more easily divisible, the speed will be faster.

But there is no ratio in which a void is exceeded by a body, just as there is none of nothing to a number. For if four exceeds three by one, and two by more than one, and one by even more than that by which it exceeds two, still there is no ratio by which it exceeds nothing; for what exceeds must be divisible into the excess plus what is exceeded, so that four will be what it exceeds nothing by plus nothing. That is also why a line does not exceed a point, if a line is not composed of points. Similarly, a void cannot bear any ratio to a plenum, so that neither can movement [in one bear any ratio to movement in the other]. Instead, if a thing spatially moves such-and-such a distance in such-and-such a time through the finest-grained medium, then through a void it exceeds every ratio. For example, let F be a void, equal to B and D. Then if A traverses and will move through it in a certain time G, less than time E, this [ratio of G to E] is the ratio that a void will bear to the plenum. In a time equal to G, however, A will traverse a part H of D. And it will surely also traverse in that time any body F that exceeds air in fine-grainedness in the same ratio as time E bears to time G. For if a body F is as much more fine-grained than D as E exceeds G, A, if it spatially moves through F, will traverse it in the same amount of time as G with a speed that is inversely proportional. If, therefore, there is no body in F, A will traverse it even faster. But the assumption was[178] that it would do so in G. So it will

178. 215ᵇ24.

traverse F in an equal time whether F is a plenum or a void. But this is impossible. It is evident, therefore, that if there is a time in which A will spatially move through any part whatever of a void, then this impossible result will follow; for it will be found to traverse in an equal time a plenum and a void; for there will be some body that bears to the other the same ratio as time does to time.

To speak in summary form, the cause of this result is clear, that between one movement and another movement there is always a ratio (for movement is in time, and between time and time there is always a ratio, provided both are limited), while between a void and a plenum there is none.

These, then, are the consequences that result from a difference in the media through which a body spatially moves. With regard to the excess of the bodies that are in spatial movement, on the other hand, they are as follows.

We see that the things that have a greater balance-weight of heaviness or lightness, other things being equal, spatially move across equal distances faster, and in accord with the ratio that their magnitudes bear to each other. So they will do so through a void as well. But this is impossible; for due to what cause will one spatially move across it faster? In plenums, indeed, this happens of necessity; for the greater one divides it faster by means of its strength; for the thing that is in spatial movement or is projected divides it either by means of its shape or by the balance-weight that it has. So [in a void] all will spatially move with equal speed. But this is impossible.

It is evident, then, from what has been said, that if there is a void what results is the contrary of what those who say that there is a void furnished one for.

Some people think that if indeed there is to be movement with respect to place, a void must exist that is intrinsically set apart. But this is the same as saying that a place is something separated; and that this is impossible was stated previously.[179]

But even if we investigate it intrinsically, the so-called void will manifestly be truly null and void. For just as, if one puts a cube in water, as much water as the cube will be displaced, so it is in the case of air too, although to perception this is unclear. And in the case of every body that can be displaced, then, it is always in the direction natural for it that it is necessarily displaced (provided it is not compressed), that is, always displaced downward (if its spatial movement, like that of earth, is downward) or upward (if fire), or in both directions—depending on whatever sort of body is inserted. But in the void this is impossible (for it is no sort of body), and [it must be that] throughout the cube an equal extent of void has penetrated, precisely the one, in fact, that was previously in the void, just as if the water or air had not been displaced by the wooden cube, but had penetrated it at every point.

Moreover, the cube, at any rate, also has a magnitude equal to that of a void it occupies. And even if this magnitude is also hot or cold, heavy or light, the being for it is nonetheless distinct from all its affections, even if not separable [from them]—I mean the volume of the wooden cube. So even if its volume were separated from all

179. 211b19–29.

the rest and was neither heavy nor light, it will occupy an equal amount of void and will be in the same part of the place and of the void as is equal to itself. How, then, will the body of the cube differ from the void or place that is equal to it? And if there are two such things, why can't there be any number whatever in the same place? This, then, is one absurd and impossible consequence.

Further, it is evident that the cube will have this same volume even if it is displaced, and all other bodies also have this feature. So, if it is no different from place, what need is there to posit a place for bodies beyond the volume of each, if the volume is without affections? For it contributes nothing, if there is another equal extended space of this sort around it.

Further, it should be clear what sort of thing a void is in things in movement. But as things stand it exists nowhere in the cosmos; for air is something, although it does not seem so—nor would water seem so to fish, if fish were made of iron; for what is tangible is judged by touch.[180]

It is clear from these considerations, therefore, that there is no separated void.

4.9
No Void in Bodies

There are some people who, because of the rare and the dense, think that it is evident that a void exists. For if rare and dense do not exist, it is impossible to contract and be compressed. But if this is not possible, either there will be no movement at all, or the whole universe will bulge, as Xuthus said, or change, for example, of air and water, must always be into equal amounts (I mean, for example, that if air comes to be from a cup of water, then at the same time from an equal amount of air that much water must have come to be), or a void must exist; for compression and expansion are not possible otherwise.

If they say that the rare is what contains many separated voids, then it is evident that, if it is no more possible for there to be a separable void than it is for there to be a place that has its own extension, neither can what is rare exist in this way. But if they say that, though it is not separable, there is nonetheless some void present within it, this is less impossible. But it follows, first, that the void is the cause not of all movement, but rather of movement upward (for what is rare is light, which is why they also say that fire is rare); and, second, that the void will be a cause of movement not in the way the medium is, but rather, just as wineskins, by being in spatial movement **217^a1** upward themselves, carry along what is continuous with them, so the void carries things upward. And yet how can there be a spatial movement of a void, or a place of a void? For what a void spatially moves into then comes to be a void of a void.

180. Rejecting the seclusion of this paragraph.

Further, in the case of what is heavy, how will they give an account of its moving downward? Also, it is clear that if the rarer and more void a thing is, the more it will be carried upward, then if it were wholly void, it would be carried fastest. But perhaps it is impossible for it even to move. And the same argument[181] that proves that all things are immovable in a void also proves that a void is immovable; for the speeds are incomparable.

Since we say that a void does not exist, and that, though the rest of the puzzle has been truly stated, either there will be no movement, if there is no condensation and rarefaction, or the heaven will bulge, or it will always be that an equal amount of water comes from air and air from water. For it is clear that a greater volume of air comes to be from water. It is necessary, then, if there is no compression, either that the next thing will be pushed outward, and so on, making the extremity bulge, or that somewhere else an equal amount of water must change from air, in order that the entire volume of the whole may be the same, or that nothing moves. For whenever there is displacement this will always happen, unless it comes around in a circle; but spatial movement is not always in a circle, but also in a straight line.

Because of these considerations, then, they would say that a certain void exists. We say, by contrast, on the basis of our assumptions, that there is one matter for the contraries (that is, of hot and cold, and the other natural contrarieties), and that what is actively comes to be from what is potentially, and that the matter is not separable, although the being for it is different, and that the matter, as it may be, of color and of hot and cold, is one in number.

Further, the matter of a body, both large and small, is the same—and clearly so; for when air comes to be from water, the same matter, not by acquiring something in addition, becomes another thing—although what it was potentially it became actively—and, again, water comes to be from air in the same way, the change being sometimes to greatness from smallness, sometimes to smallness from greatness. In the same way, therefore, if much air comes to occupy a smaller volume, or when from a smaller one it comes to be a greater, it is the matter, which is potentially both, that comes to be one or the other. For just as the same matter comes to be hot from cold and cold from hot, because it was so potentially, in the same way from being hot it comes to be more hot, though nothing in the matter comes to be hot that was not hot when the thing was less hot. Just as indeed if the arc or convexity of a larger circle comes to be that of a smaller circle (whether or not it is the same arc), what is convex has not come to be in anything that was not convex but straight (for it is not by there being intervals that there is less or more). Nor can we take any magnitude of flame in which hotness and whiteness[182] are not present. In the same way, therefore, the former heat is related to the later one. Thus both the greatness and smallness of the perceptible volume are extended not because of the matter acquiring something

181. 215a29–216a11.
182. I.e., brightness.

in addition, but because it is potentially the matter of both, so that the same thing is dense and rare, and the matter of them is one.

{Further, just as the arc of a circle when contracted into a smaller space does not acquire some other part that is convex, but rather what was there has been contracted; and just as any part of fire that one takes will be hot; so too all cases that are by contraction and expansion[183] are of the same matter.}[184]

The dense is heavy and the rare is light. For there are two sorts in each case, that is, of the dense as well as of the rare; for both the heavy and the hard seem to be dense, and their contraries, the light and the soft, to be rare. The heavy and the hard clash, however, in the case of lead and iron.

From what has been said, then, it is evident that a void does not exist either set apart—whether unconditionally or in the rare[185]—or potentially, unless one wishes, no matter what, to call the cause of spatial movement a "void." In that sense, the matter of the heavy and the light, insofar as they are such, would be the void; for the dense and the rare are, with respect to this contrariety, productive of spatial movement, and with respect to the hard and the soft, productive of being affected and not being affected—not a cause of spatial movement but rather of alteration.

Concerning the void, then, both the way it exists and the way it does not, let things be determined in this way.

4.10
Puzzles and Views about Time

After what has been said, the next thing to go through is time. First, it is well to go through the puzzles about it, and through the external accounts, to see whether it is among the beings or the non-beings, and then what its nature is.

That time either does not exist at all or does so scarcely or in a vague way might be suspected on the basis of the following considerations:

One part of time has been and is not, while another part of it will be and is not yet. And from these both unlimited time and whatever time is taken on any given occasion are composed. What is composed of non-beings, however, might seem to be **218^{a}1** incapable of participating in being.

In addition, in the case of everything that is divisible into parts, if it is, it is necessary that, when it is, either all or some of its parts must be. In the case of time, by contrast, although it is divisible into parts, some parts have been, some parts are to

183. Reading συναγωγῇ καὶ διαστολῇ.
184. Accepting the seclusion of this near doublet of 217^{b}2–7.
185. I.e., as gaps inside a body.

be, but none is. But the now[186] is not a part [of time]; for a part is measured,[187] and the whole is composed of [its] parts. But time does not seem to be composed of nows.

Further, it is not easy to see whether the now, which appears to divide the past from the future, remains one and the same on all occasions, or is a distinct thing again and again. For if it is always a distinct one again and again, and if the parts of time that are distinct again and again are not simultaneous (unless one encompasses and the other is encompassed, as the shorter time is encompassed by the longer), and if the now that is not but was previously must have passed away at some moment, then the nows will not be simultaneous with each other either, and it must always be that the previous now has passed away. But it cannot have passed away in itself, because it existed then, while it is impossible for a previous now to have passed away in another now. For we take it that it is impossible for nows to be contiguous to each other, as it is for a point to be contiguous to a point. If indeed, then, it has not passed away in the next now, but in another one, it will be simultaneously in the nows in between them, which are unlimitedly many. But this is impossible.

But then it is not possible either for the now to remain the same on all occasions; for nothing that is divisible and limited has [only] one limit, whether it is continuous in one direction or in more than one; but the now is a limit, and it is possible to take a limited time. Further, if to be together with respect to time, and neither before nor after, is to be at one and the same now, and if earlier and later nows are at this very now, then events of ten thousand years ago will be simultaneous with events of today and nothing will be either before or after anything else.

So much, then, by way of going through the puzzles concerning the things that belong to time.

As to what time is, and what its nature is, this is left equally unclear both by what has been handed down to us and by our own previous discussions. For some say that it is the movement of the whole universe,[188] others that it is the sphere itself.

218b1 And yet a part of the revolution of the universe is also a time, but the revolution certainly is not; for what was taken was a part of a revolution, not a revolution. Further, if there were more than one heaven, the movement of any whatever would equally be time, so that many distinct times would be together.[189]

The sphere of the whole universe was believed to be time by those who said it was, because everything is both in time and in the sphere of the whole universe. But this view is too simpleminded for us to investigate its impossible consequences.

186. 233b33–35.

187. Reading μετρεῖται.

188. E.g., Plato, *Timaeus* 38c, 39d.

189. Suppose U_1, U_2, and U_3 are different universes, each revolving at different speeds. P is some temporal process. Measured by U_1, the answer is t_1, by U_2, t_2, and by U_3, t_3. By hypothesis $t_1 \neq t_2 \neq t_3$. Yet since each measures P correctly, $t_1 = t_2 = t_3$. So that different times are together (or simultaneous).

But since time seems most of all to be a sort of movement and change, this we must investigate. The change and movement of a given thing is only in the thing that is changing, or wherever the thing itself that is moving and changing happens to be. Time, by contrast, is present equally everywhere and where everything is. Further, change is faster or slower, while time is not; for the fast and slow are defined by time—fast being what moves much in little time, slow what moves little in much time. Time, however, is not defined by time, neither by its being so much nor by its being of a certain sort. It is evident, therefore, that time is not a movement—and it makes no difference to us at present whether we speak of movement or of change.[190]

4.11
What Time Is; the Now

But then neither does time exist without change; for when we ourselves do not change in our thought or do not notice that we change, then it does not seem to us that time has passed, just as it does not seem to have done so to the fabled sleepers among the heroes in Sardinia when they wake up;[191] for they join together the earlier now to the later now and make them one, omitting what is in between because of their lack of perception. So just as, if the nows were not distinct but one and the same, there would not have been time, in the same way when they are distinct, but are not noticed to be distinct, what is in between does not seem to be a time. If, then, our not thinking that there is time happens to us when we do not distinguish any change whatever, but rather the soul seems to remain in one indivisible now, and that when we perceive and distinguish, we say that some time has passed, it is evident that time does not exist without movement and change. It is evident, then, that time neither is movement nor does it exist without movement. And since we are **219^{a}1** inquiring about what time is, we must start from this, and ask what thing belonging to movement time is.

For we do perceive movement and time together; for even when it is dark and nothing affects us through the body, but there is some movement in the soul, it immediately seems to us that some time has also passed. Moreover, when some time seems to have passed, some movement also seems to have occurred together with it. So time is either movement or something belonging to movement. Since, then, it is not movement, it must be something belonging to movement.

Since what is moving moves from something to something, however, and since every magnitude is continuous, the movement follows along with the magnitude; for because the magnitude is continuous, the movement is also continuous, and

190. $225^{a}34$–$^{b}9$.

191. According to one account, sick people received a treatment in Sardinia that involved sleeping among the dead heroes there for five days, after which they awoke remembering nothing.

because the movement is continuous, the time is too; for whatever the length of the movement is, that always seems to be the length of the time that has passed as well. The before and the after are primarily in place, then, and there they are in accord with their position. And since the before and the after are in the magnitude, it is necessary that the before and the after are also in the movement, by analogy with the ones there. But then in time too the before and the after are present, because of the one always following along with the other of them. The before and the after in movement are that thing, whatever it is, by being which movement exists,[192] but the being for it is distinct and not a movement.

But then again we come to know time once we distinguish movement, defining it by the before and the after. And we say that time has passed when we get a perception of the before and the after in movement. And we define it by grasping one [now][193] and then another, and something else in between them; for whenever we understand the extremes to be distinct from what is intermediate, and the soul says that the nows are two, one before and the other after, it is then, and it is this, that we say time is; for what is defined by the now is believed to be time—and we may assume this.

Whenever, then, we perceive the now as one, and not either as before and after in the movement or as the same but belonging to something that is before and after, no time seems to have passed, because there seems to have been no movement either. But whenever we do perceive the before and the after, then we say that there **219b1** is time; for time is this: a number belonging to movement with respect to the before and the after.

Therefore, time is not movement, but rather that thanks to which movement has a number. There is sign of this; for we judge more and less by number, but more or less movement by time. Therefore, time is a sort of number. Since, though, number is twofold (for both what is counted or what is countable and what we count them with are called "number"), time is, then, what is counted and not what we count by. And what we count by is distinct from what is counted.

Also, just as movement is always distinct again and again, so too is time (but all simultaneous time is the same; for the now, whichever now it is, is the same—though the being for it is distinct—and the now measures time, insofar as it determines a before and an after[194]).

But the now is in a way the same and in a way not the same; for insofar as the now is in something that is different again and again, it is distinct (this is what it

192. Reading ἐστιν. The phrase refers not to the being for, or essence of, movement but to the ground of that essence.

193. Reading αὐτό.

194. Reading τὸ δὲ νῦν τὸν χρόνον μετρεῖ, ᾗ πρότερον καὶ ὕστερον ὁρίζει. Suppose that M_1, M_2, and M_3 are distinct movements, whose starting-points are simultaneous, and suppose that times N_1, N_2, and N_3 are the nows that give them definition, or mark them off, at that point. Then, since simultaneous nows are identical (219b10), $N_1 = N_2 = N_3$, but they differ in being because N_1 marks the start of M_1, not that of M_2 or M_3, and so on.

is for it to be a now), while the now, as that (whatever it is) by being which it is [what it is], is the same. For, as we said,[195] movement follows along with magnitude, and time follows along with movement, as we are saying here; and as in the case of the point, so likewise in the case of the thing in spatial movement by which we come to know movement and the before and the after in it. And what is in spatial movement, in respect of that thing (whatever it is) by being which it is [what it is], is the same (whether a point, a stone, or something else of this sort), but in account it is distinct—just as the sophists take Coriscus-in-the-Lyceum and Coriscus-in-the-marketplace to be distinct.[196] What is in spatial movement, then, is distinct by being in distinct places, and the now follows along with what is in spatial movement, just as the time does with the movement (for it is by what is in spatial movement that we know the before and the after in movement, and the before and the after insofar as they are countable is the now). So in this case too that thing (whatever it is), by being which the now is [what it is], is the same (for it is the before and the after in movement), although the being for it is different (for that by means of which the before and the after are countable is the now).

And it is this that is most of all known; for the movement too is known by what is moving and spatial movement by what is in spatial movement; for what is in spatial movement is a this something, while the movement is not. In one way, then, the now is always the same, and in another way not the same; for what is in spatial movement is so too.

It is evident too that if time did not exist, the now would not, and if the now did not, time would not; for just as what is in spatial movement and its spatial movement are together, so too are the number of what is in spatial movement and the number of its spatial movement.[197] For the number of the spatial movement is time, while the now corresponds to what is in spatial movement, as a sort of unit of number.

Also, time is both continuous in virtue of the now and divided at the now; for this too follows along with the spatial movement and what is in spatial movement. For in fact the movement (that is, the spatial movement) is one in virtue of what is in spatial movement, because it is one—and not because that thing (whatever it is), by being which it is [what it is], is one (since that might leave intervals), but rather because it is one in account.[198] And this is what gives definition to the movement as movement before and movement after.

195. 219^a11–12.

196. *Met.* 1026^b15–18.

197. M_1 and M_2 are spatial movements. If they are two distinct but contiguous stages in the same movement, they must be contiguous states in the movement of the same spatially moving object O_1. Similarly, if the time t_1 that M_1 takes is to be contiguous to the time t_2 that M_2 takes, then the now N_1 that marks the end of t_1 must be coincident with the now that marks the beginning of t_2, or vice versa. Thus N_1 unifies t_1 and t_2 in the way that O_1 unifies M_1 and M_2.

198. The thing (whatever it is), by being which a spatially moving object O_1 is what it is, is O_2, the object that is in fact in spatial movement M_1 but could be at rest. It is not O_2 that makes M_1 one movement, since O_2 might alternately move and rest. Instead it is O_1 that makes M_1

In this respect too the now follows along in a way with the point; for the point also both makes the length continuous and gives it definition; for it is the start of one length and the end of another. But when one takes it in this way, treating the one point as two, one must come to a stop, if the same point is going to be start and end. The now, on the other hand, because what is in spatial movement is in movement, is always a distinct one.

So time is a number, not as being the number of the same point, because the latter is both start and end, but more of the points as the extremes of the line, and not as the number of the parts—both because of what was said (for we can treat the middle point as two, so that being at rest will result), and further, because it is evident that the now is no part of time, nor the division a part of the movement, any more than the point is a part of the line (on the contrary, it is the two segments that are parts of the one line). Insofar as the now is a limit, then, it is not time, but rather a coincident of it, while insofar as it counts, it is a number; for limits belong only to what they are the limits of, while the number of these horses—ten—is elsewhere too.

It is evident, therefore, that time is a number belonging to movement with respect to the before and the after, and that it is continuous; for what it belongs to is continuous.

4.12
Various Affections of Time; What It Is to Be in Time

The smallest number unconditionally is the two.[199] But of a sort of number there is in one way a smallest, in another way not—for example, of a line, the smallest number in plurality is two lines (or one line), but in magnitude there is no smallest; for every line can always be divided. So it is with time too; for the smallest [time] in number is the one or the two, but in magnitude there is none.

220b1 It is evident too that time is not said to be fast or slow, but much or little, and long or short. For insofar as it is continuous it is long or short, while insofar as it is a number it is much or little. But it is not fast or slow; for no number with which we count is fast or slow either.

Also, it is the same time everywhere at once, but not the same time before and after, because the present change[200] is also one, while the past change and the future change are distinct. And time is not the number by which we count but the number

---

one movement. It does this, however, not by being one in number but by being one in account. For O_1 is a distinct thing on each occasion, just like the now (219b31–33). But of all these distinct things the account is "O_1 spatially moving from place P_1 to place P_2," where P_1 and P_2 are coincident with the nows N_1 and N_2 that give definition to M_1 by being its starting- and end-points.

199. *Met.* 1056b25–27, 1088a4–8.

200. I.e., a particular change whose starting-point is coincident with the present now.

that is counted, and this, occurring before and after, is always distinct; for the nows are distinct. The number of a hundred horses and of a hundred human beings is one and the same, but the things—the horses and the men—it is a number of are distinct. Further, in the way that a movement can be one and the same again and again, so too can a time—for example, a year, a spring, or a fall.

Not only do we measure the movement by the time, but also the time by the movement, because they are given definition by each other; for the time gives definition to the movement (for it is its number), and the movement to the time. And we speak of much time and little time, measuring it by the movement, just as we measure the number by what is countable—for example, by the one horse we measure the number of horses. For it is by the number that we know the quantity of horses, and, conversely, by the one horse that we know the number of horses itself. It is the same way in the case of time and movement; for we measure the movement by the time and the time by the movement. And it is reasonable that this has happened, because the movement follows along with the magnitude and the time with the movement, for they are a quantity, divisible, and continuous; for it is because the magnitude is like this that the change has these affections and because movement is like this that time does. And we measure both magnitude by movement and movement by magnitude; for we say that road is long, if the journey is long, and that the latter is long, if the road is long, and that the time is, if the movement is, and the movement, if the time.

Since time is a measure of movement, however, and of being moved, and since it measures a movement by defining some movement that will measure out the whole (just as the cubit measures length by defining some magnitude that will measure out the whole), and for a movement to be in time is for both it and the existence of it to be measured by time (for time at once measures the movement and the existence of the movement), this is what it is for it to be in time, for its existence to be measured; it is clear, though,[201] that for other things too this is what it is to be in time: it is for their existence to be measured by time.

For to be in time is one or other of two things: to be when time is, or in the way that we say of some things that they are in number. The latter signifies either what is a part or affection of number, or, in general, something that belongs to number, or that there is a number of it. And since time is a number, the now, the before, and everything of this sort are in time in the way in which the unit and the odd and the even are in number (for the latter are something belonging to number, as the former are something belonging to time). Things, by contrast, are in time as they are in number. And if this is so, they are encompassed by time, just as things in number are encompassed by number, and things in place by place.

It is evident too that to be in time is not to be when time is, any more than to be in movement or in place is to be when movement is or when place is. For if this is

201. Reading δῆλον δὲ.

what being in something is to be, then all things will be in anything whatever, and the heaven will be in a grain of millet; for when the grain is, the heaven is too. But this is coincidental, while the other follows of necessity, and for what is in time there must be a certain time when that thing is too, and for what is in movement, there must be movement at that time.

But since what is in time is so as in number, a time may be taken that is greater than that of all that is in time, which is why it is necessary for all things in time to be encompassed by time, just like the other things that are in something—for example, the ones in place that are encompassed by place. And a thing is affected in some respect by time, just as we are accustomed to say that time dissolves things, that everything grows old due to time, and forgets because of time, but not that it learns because of time, becomes young, or becomes beautiful; for time is intrinsically a cause rather of passing away [than of coming to be]; for it is the number of movement, and movement removes what is present.

So it is evident that the things that always are, insofar as they always are, are not in time; for neither are they encompassed by time nor is their being measured by time. A sign of this is that they are not affected by time either, suggesting that they are not in time.

Since time is the measure of movement, however, it will be the measure of rest too; for all rest is in time. For it is not the case that, as everything in movement must move, so it must be too with what is in time; for time is not movement, but the number of movement, and it is also possible for what is at rest to be in the number of movement. For not everything that is unmoving is at rest, but only what, though lacking movement, is naturally able to move itself, as was stated in the previous discussion.[202]

For a thing to be in number is for there to be some number of the thing, and for the being of it to be measured by the number in which it is, so that if it is in time, by time. And time will measure what is moving and what is at rest, insofar as the one is moving and the other is at rest; for it will measure the movement and the rest, saying of what quantity each is. So what is moving, insofar as it is some quantity, will not be measurable by time simply, but insofar as its movement is of some quantity. So none of the things that are neither in movement nor at rest are in time; for to be in time is to be measured by time, and time is a measure of movement and rest.

It is evident, then, that not every non-being will be in time—for example, all the ones that do not admit of being otherwise, such as the diagonal's being commensurable with the side. For, in general, if time is intrinsically a measure of movement and of other things coincidentally, it is clear that for the ones whose being it measures, for all of them, their being lies in being at rest or moving. Those things, then, that admit of passing away and coming to be and, in general, that at some time are and at some time are not, must be in time (for there will be some greater time that will exceed

202. 202a4–5.

both their being and what measures the existence of them). By contrast, non-beings that were (for example, Homer once was) or ones that will be (for example, something in the future) are encompassed by time on whichever of the two sides of the present it encompasses them, and if on both sides, both. But those that time in no way encompasses neither were nor will be. And these are the sorts of non-beings whose opposites always are, as the diagonal's being incommensurable always is, and this will not be in time. Nor, therefore, will its being commensurable be in time. That is why it always is not: because it is the contrary of what always is. As for those things where it is not the case that the contrary always is, these are capable of being and of not being, and there is a coming to be and passing away of them.

4.13
What Now, at Some Time, Just, Recently, Long Ago, and Suddenly Are

The now is a continuity-maker for time, as was said;[203] for it makes past and future time continuous. And it is, in general, a limit[204] of time; for it is a starting-point of one time and an end-point of another, although this is not evident, as it is in the case of the point remaining where it is. It divides potentially, and insofar as it does so the now is always a distinct one, while insofar as it binds together it is always the same,[205] just as in the case of mathematical lines (for to the understanding it is not always the same point; for it divides in distinct places on distinct occasions; but insofar as it is one, it is the same on all). So too the now is, on the one hand, a potential divider of time, and, on the other hand, the limit and unifier of both segments. But the division and the unification are the same and with respect to the same thing, but their being is not the same.

This, then, is one way in which things are said to be now. Another is when the time of something is near at hand: he will come now, because he will come today; he has now come, because he came today. But the events in the *Iliad* have not happened now, nor is the flood now; and yet the time leading to them is continuous, but they are not near at hand.

---

203. 220^a5.

204. Reading ὅλως πέρας.

205. Unlike a point p on a spatial line L, at which L can be actually divided into two disjoint line segments L_1 and L_2, a now N_1, which is coincident with time t_1 in a temporal series S, cannot actually divide S into two disjoint temporal series, since time cannot stop and start in the requisite way. Instead N_1 divides S potentially at t_1, into S_1 (times earlier than t_1) and S_2 (times later than t_1). But to do so it must be distinct from all the times in S_1 and all the times in S_2, and so from all the nows coincident with those times. The now that binds together S_1 and S_2, by contrast, must be coincident with a time t_x in S_1 and with a time t_y in S_2, and so must always be the same now, since coincident (or simultaneous) nows are identical. Think of t_x as the last point in S_1 and t_y as the first point in S_2; these must be coincident if S is to be a continuous time.

And the "at some time" is defined relative to the first sort of now[206] (for example, at some time Troy was taken, and at some time there will be a flood); for the time must be limited relative to the now. There will, therefore, be a certain quantity of time from this to that [future one], and there was a certain quantity to the past one. But if there is no time that is not "at some time," every time will be limited.

Will time, therefore, give out? Or will it not do so, if indeed there is always movement? Will a time, then, [always] be a distinct one, or the same one many times over? It is clear that time exists in the same way that movement exists; for if one and the same movement comes to be at some time, the time too will be one and the same, and if not, it will not be. But since the now is an end-point and a starting-point of time, though not of the same time, but rather is an end-point of past time and a starting-point of future time, then, just as the circle has its convexity and concavity in the same thing in a way, so too time is always at a starting-point and at an end-point. And because of this it seems to be always distinct; for the now is not the starting-point and end-point of the same thing; for otherwise contraries would hold of it at the same time and in the same respect. Time will not give out, then; for it is always at a starting-point.[207]

The "just" is the part of future time that is close to the present indivisible now: When are you taking a walk? I'm just taking it (because the time in which the person is going to take it is near at hand). Or, it is the part of past time that is not far from the now: when are you taking a walk? I've just taken it. But to say that Troy has just been taken—we do not say that, because it is too far from the now. The "recently" is part of the past that is close to the present now: When did you come? Recently (if the time is near to the presently existing now). What is far away from now is "long ago." The "suddenly" is what departed from its former condition in a time that is imperceptible because of its smallness. {And all change is a departure from a former condition.}[208]

It is in time that all things come to be and pass away. That is why some people called it the "wisest" of all things, while Paron the Pythagorean, speaking more correctly, called it the "most ignorant," because people forget in time. It is clear, then, that it will be intrinsically the cause of passing away rather than of coming to be, as was stated earlier[209] (for change is intrinsically a departure from a former condition), but it is coincidentally a cause of coming to be and of being. An adequate sign of this is that nothing comes to be without its being moved in some way and being affected,[210] while a thing may pass away even though it does not move at all. And this above all is what is usually said to be passing away due to time. Nevertheless, time does not produce even this change, although it happens that it too occurs in time.

206. 222[a]20–21.
207. 251[b]19–23.
208. Secluded as a near doublet of ἐκστατικὸν γὰρ ἡ μεταβολὴ καθ' αὑτήν at 222[b]21.
209. 221[b]1–3.

That time exists, then, and what it is, and in how many ways something is said to be now, and what at some time, recently, just, long ago, and suddenly are, has been stated.

4.14
Before in Time; Time and the Soul

With these issues determined by us in this way, it is evident that every change and everything in movement is in time. For the faster and slower exists with respect to every change (for it is seen in every case). By something's "moving faster" [than another] I mean that it changes before the other into the given condition, when it covers the same distance with a regular movement—for example, in the case of spatial movement, if both things move along the circumference of a circle, or both along a straight line, and similarly in all other cases. But then what is before is in time; for we say before and after with respect to the distance from the now, and the now is the defining mark between the past and the future. So since the nows are in time, the before and the after will also be in time; for what the now is in, the distance from the now will be in too. (Things, though, are said to be before in contrary ways with respect to past time and future time. For in the past we say that what is before is further from the now, what is after nearer to it, while in the future we say that what is before is nearer, and what is after further.) So since the before is in time, and the before goes along with every movement, it is evident that every change and every movement is in time.

It is also worth investigating how time is any way related to the soul, and why time seems to be in everything—on earth, in the sea, and in the heaven. Or is it because time is an affection or state of movement, since it is in fact the number of it, and because all these things are movable (for they are all in place), and time and movement are together, both potentially and actively?

One might raise a puzzle, however, as to whether if soul did not exist, time would exist or not. For if it is impossible for there to be something to do the counting, it is also impossible for anything to be countable, so that it is clear that number would not exist either. For a number is either what has been counted or what can be counted. But if there is nothing that has it in its nature to do the counting other than soul, and—of soul—understanding, then it is impossible for time to exist if the soul does not exist, except that there might be that thing (whatever it is) by being which time is [what it is]—for example, if it is possible for movement to exist without soul. But the before and the after are in a movement; and time is these insofar as they are countable.

One might also raise a puzzle, however, as to what sort of movement time is the number of. Or is it of any sort whatever? For things come to be and pass away, and increase, alter, and spatially move in time. Insofar as each is a movement, then, to this

extent time is its number. That is why it is unconditionally the number of continuous movement, and not of a particular sort of it. But [it might be objected] it is possible
223ᵇ1 that now another thing has also moved, with time being the number of each of the two movements. Is there, then, a distinct time, and will there be two equal times at once? Or is this not so? For a time that is both equal and together is one and the same time, and even those that are not together are the same in form; for suppose there are
5 dogs and horses, seven of each, the number is the same. In the same way, movements that have limits that are together take the same time, although one perhaps is fast and the other not, one a spatial movement and the other an alteration. Yet the time of the alteration and of the spatial movement is the same, if indeed it is the case both that its number[211] is equal and [their limits] together. And this is why, while movements
10 are distinct and separate, time is the same everywhere, because the number belonging to things that are equal and together is also one and the same everywhere.

But since there are spatial movements and, among them, the circular movement, and each thing is counted by some one thing of the same kind, units by a unit, horses by a horse, and in the same way time by some definite time, and since, as we said,[212]
15 time is measured by movement as well as movement by time (and this is so because the quantity of the movement and the quantity of the time is measured by a movement defined by the time)—if, then, what is first is the measure of all things of the same kind, regular circular spatial movement is most of all a measure, because the number of
20 it is most known. (Neither alteration, nor increase, nor coming to be are regular, while spatial movement is.) That is why time is thought to be the movement of the sphere;[213] because the other movements are measured by this one, and time by this movement.

This is also why the customary saying comes about; for it is said that human affairs
25 go in a circle, as do the other things that have a natural movement and coming to be and passing away. And this is so because all other things are judged by time, and get an end-point and a starting-point as if in accord with a certain temporal cycle. For even time itself is thought to be a sort of circle, and this, in turn, is thought because
30 it is the measure of this sort of spatial movement, and is itself measured by this sort. So to say that those things that come to be go in a circle is to say that there is a certain circle of time, and this is so because it is measured by the circular spatial movement; for the measured thing[214] appears to be nothing beyond the measure, while the whole
224ᵃ1 universe involves a plurality of measures.[215]

211. Reading ὁ ἀριθμὸς.
212. 220ᵇ23–24.
213. I.e., the sphere of the whole universe (218ᵇ5–7).
214. Reading τὸ μετρούμενον.
215. Aristotle is explaining how people came falsely to think that time itself is a sort of circle. When they looked at the measured thing they saw nothing beyond the measure, namely, the circular spatial movement of the sphere (223ᵇ30–31). But had they looked at the other regular movements within the sphere, which are equally good measures of time, they would have seen that time cannot be identical to any one of them.

It is also correctly said, however, that the number of the sheep and that of the dogs is the same number, if the two numbers are equal, but they are neither the same ten nor ten of the same things, just as the equilateral and the scalene are not the same triangles, and yet they are the same figure, because both are triangles; for things are said to be the same if they do not differ by a differentia, but not if they do—for example, triangle differs from triangle by a differentia of triangle (therefore, they are then distinct triangles), but they do not differ by one of figure, but are in one and the same division of it. For such-and-such sort of figure is a circle, and such-and-such sort a triangle, and, of this, such-and-such sort is equilateral, and such-and-such sort scalene. They are, then, the same figure, and this a triangle, but not the same triangle. The numbers [we are discussing], then, are also the same number (for one does not differ from the other by a differentia of number), but is not the same ten; for the things of which it is said differ; for the one lot are dogs and the other lot horses.

Time—both time itself and the topics that properly belong to its investigation—has now been spoken about.

BOOK 5

5.1
Classification of Movements and Changes

Among all things that change, some change coincidentally, as when we say that the musical walks, because something that is coincidentally musical walks; others are said simply to change, because something in them changes—for example, those said to change in respect of their parts (for the body becomes healthy, because the eye or the chest does, and these are parts of the whole body); and there is also something that is moved neither coincidentally nor in virtue of something else belonging to it, but is itself moved primarily. And this is the intrinsically movable, but with respect to distinct sorts of movement, it will be distinct—for example, alterable. And within the sphere of alteration, curable is distinct from heatable. It is the same way in the case of the mover; for one thing causes movement coincidentally, another in virtue of a part in it, another intrinsically and primarily—for example, the doctor cures, and the hand strikes a blow.

There is, then, a thing that causes movement primarily; a thing that is moved; further, that in which, the time; and, beyond these, that from which and that to which; for every movement is from something to something; for the thing primarily moved is distinct from that to which and that from which it is caused to move—for example, wood, hot, cold, of which the first is the thing, the second, that from which, **$224^{b}1$**

the third, that to which. But[216] it is clear that the movement is in the wood, not in the form; for the form neither causes movement nor is moved, and the place and the quantity do not do so either. On the other hand, there is the mover, the moved, and that to which it is moved. And it is the to which rather than the from which that the change is named after. That is why passing away is a change to non-being, even though what passes away also changes from being, and why coming to be is a change to being, and yet it is also a change from non-being.

We stated earlier what movement is.[217] But the forms, affections, and the place to which moving things are moved are immovable—for example, scientific knowledge and heat. And yet one might raise a puzzle as to whether affections (paleness being an affection) are movements: but then[218] there will be change to a movement. But presumably it is not paleness that is a movement, but turning pale. And in these cases too there is what is coincidental (what is in virtue of a part or what is in virtue of something else) and what is primarily and not in virtue of anything else—for example, a thing that is turning pale changes coincidentally to a thing being understood (for the color is coincident with its being understood), it changes to color, because pale is a part of color (and to being in Europe, because Athens is part of Europe), but it changes intrinsically to the color pale.

It is clear, then, in what way a thing is in movement intrinsically, coincidentally, or in virtue of something else; and—in the case both of the mover and of the moved—in what way in respect of something else and in what way by itself primarily; and it is also clear that the movement is not in the form but in the thing that is moving, that is, in what is actively movable.

Coincidental change we may set aside; for it exists in all things, at all times, and in all respects. Change that is not coincidental, by contrast, is not found in everything, but rather in contraries, their intermediates, and contradictories. We may be persuaded of this by induction. Something changes from an intermediate; for it uses the intermediate as a contrary in relation to either of the two contraries; for the intermediate is in a way the extremes.[219] That is why we speak of it in relation to them, and them in relation to it, as in a way contraries—for example, the middle note is low-pitched in relation to the highest-pitched and high-pitched in relation to the lowest-pitched, and gray is white in relation to black and black in relation to white.

And since every change is from something to something—as the name (*metabolê*) itself makes clear, indicating something after (*meta*) something else, that is, one thing earlier and another later—what changes must change in one of four ways: from an underlying subject to an underlying subject; from an underlying subject to what is not an underlying subject; from what is not an underlying subject to an underlying subject; or from what is not an underlying subject to what is not an underlying

216. Reading δὲ.
217. 201ᵃ10–11.
218. Reading δὲ.
219. *Met.* 1057ᵃ18–19.

subject (I mean by "underlying subject" what is made clear by an affirmation[220]). So it is necessary on the basis of what has been said that there are three sorts of change: that from an underlying subject to an underlying subject; that from an underlying subject to what is not an underlying subject; and that from what is not an underlying subject to an underlying subject. For there is no change from what is not an underlying subject to what is not an underlying subject, because there is no opposition; for the terms are not contraries nor is there any contradiction involved.

A change from what is not an underlying subject to an underlying subject, that is, a change in accord with contradiction, is a coming to be—an unconditional coming to be when the change is unconditional, in a certain respect when the change is in a certain respect. For example, a change from not pale to pale is a coming to be in this respect, pale, while a change from unconditionally not being to substance is unconditional coming to be, with respect to which we say that a thing comes to be unconditionally, not that it comes to be something.

A change from an underlying subject to what is not an underlying subject is a passing away—an unconditional one when the change is from substance to not being, in a certain respect when the change is to the opposite contradictory, as was said in the case of coming to be.

If things are said not to be in many ways, and there can be movement neither of what by composition or division is not[221] nor of what potentially is, which is the opposite of what actively is unconditionally (for although what is not pale or not good may nonetheless be in movement coincidentally, for what is not pale may be a human, still what is unconditionally not a this [something] cannot in any way be in movement), then it is impossible for what is not to be in movement (and if this is so [it is equally impossible] for coming to be to be a movement; for, indeed, [we may say that] what is not comes to be [something]; for to whatever extent it comes to be [something] coincidentally, it is nonetheless true to say that it belongs to what is not to unconditionally come to be)—and it is likewise impossible for what is not to be at rest.

There are these difficulties, then, with the being in movement of what is not,[222] and another arises if all things that are in movement are in a place and what is not is not in a place; for then it would be somewhere.

Passing away, then, is not a movement either; for the contrary of a movement is either a movement or rest, while passing away is the contrary of coming to be.

Since, then, every movement is a sort of change, and changes are the three sorts we mentioned, and since among these changes, coming to be and passing away are not movements, and movements are changes with respect to contradictories, it necessarily follows that only change from an underlying subject to an underlying subject **$225^{b}1$**

220. $225^{b}3$–5.

221. What is not by combination is an untrue affirmative; what is not by division is an untrue negative.

222. Retaining τῷ κινεῖσθαι τὸ μὴ ὄν.

is movement. And underlying subjects are either contraries or intermediates (for a privation may be posited as a contrary), and may be made clear by an affirmation, [like] naked, toothless, or black.

If, then, the categories are distinguished as substance, quality, place, time,[223] relative, quantity, and affecting or being affected, it necessarily follows that there are three sorts of movement—that of a quality, that of a quantity, and that with respect to place.

5.2
Classification of Intrinsic Movements; Immovability

There is no movement with respect to substance, however, because there is no contrary to substance among the beings. Nor is there with respect to[224] the relative; for when one of the two relata changes,[225] it may be true that the other does not change at all, so that the movement of them is coincidental. Nor is there movement of affecting or being affected, or of any[226] mover and any moved, because there is no movement of movement nor coming to be of coming to be, nor, in general, change of change.

For, in the first place, there are just two ways in which there might be movement of movement: As an underlying subject (for example, as a human is in movement because he changes from pale to dark), so that in this way the movement too might be heated or cooled, change its place, increase or decrease. But this is impossible; for a change is not a sort of underlying subject. Or some other underlying subject might change from one change to some other forms [of change], like a human does from sick to healthy.[227] But this is not possible either, except coincidentally; for this[228] movement is a change from one form to another. (Coming to be and passing away are also like that, except that they are to things opposed in one way, while the other—movement—is to things opposed in another way.) A thing changes at the same time from health to sickness, then, and from this change itself to another. It is clear, then, that when it has become sick, it will have changed to whatever the other sort of change may be (for it may remain at rest), and never to some random sort. And this new change will be from something to something else, so that this will in fact be the opposite change: becoming healthy. But [we will respond that] this is by coincidence, as there is change from recollecting to forgetting, because what these belong to changes, now to scientific knowledge, now to health.[229]

228. Reading αὕτη.
229. Reading ὑγίειαν.

Further, it will go on without limit, if there is to be change of a change and coming to be of a coming to be. If the later is so, then the earlier must also be so. For example, if the simple coming to be was at some time coming to be, what comes to be something was also at some time coming to be. So what simply comes to be something was not yet there, but there was already something that was coming to be coming to be something. And again this was at some time itself coming to be, and so it was not yet at that time coming to be coming to be. But since in an unlimited series there is no first term, there will be no first here either, and so neither will there be a following one. Nothing, then, can either come to be, move, or change.

Further, the same thing that admits of movement also admits of the contrary movement (and further, of coming to rest), and of coming to be and passing away. So what is coming to be coming to be is passing away when it has come to be coming to be. For it cannot pass away as soon as it is coming to be, nor after it has come to be, since what is passing away must be.

Further, there must be a matter that underlies both what comes to be and what changes. What, then, will it be? What is it that becomes a movement or a coming to be, as a body or a soul is what undergoes alteration? And, again, to what do they move? For it[230] must be the movement or coming to be of something from something to something. But how will it also be at the same time? For the coming to be of learning is not learning, and so no coming to be of a coming to be is a coming to be, and nor can any specific coming to be be a coming to be of a specific coming to be.

Further, if there are three forms of movement, then the underlying nature and that to which it proceeds must be one or other of these—for example, a spatial movement must be altering or in spatial movement.

In general, then, since everything is moved in one of three ways, either coincidentally, in virtue of a part of it, or intrinsically, change can change only coincidentally, as when the one being cured runs or learns. And coincidental change we set aside not long ago.[231]

Since there is no movement either of substance or of the relative or of affecting and being affected, it remains for movement to be with respect to quality, quantity, and place. For in each of these there is contrariety. Movement with respect to quality we may call "alteration," since it has been joined to this common name. By "quality" I mean not what is in the substance (for even the differentia is a quality[232]), but the affective quality in virtue of which a thing is said to be capable of being affected or to be unaffectable. Movement with respect to quantity, as regards its common feature, has no name, but with regard to each of its two varieties it is called "increase and decrease"—that to the complete magnitude being increase, that away from it being decrease. Movement with respect to place has neither a common nor a special name,

230. Reading τι.
231. $224^{b}26$–27.
232. *Met.* $1020^{a}33$–34.

but we may call the common sort "spatial movement," and yet things are said to be spatially moving in the strict sense only when, without its being up to them, they change their place, to stop [moving], as are things that do not move themselves with respect to place.

226[b]1 Change within the same form but with respect to the more and the less is alteration; for it is movement from a contrary to a contrary, whether unconditionally or to some degree; for when it proceeds to the less, it will be said to be changing to the contrary, and when to the more, from the contrary to the affection itself. For it makes no difference whether the changing is to some degree or unconditional, except that in the former case the contraries will have to be present only more or less. And the more and the less is the presence or absence of a greater or lesser degree of the contrary [of the affection].

On the basis of these considerations, then, it is clear that there are [only] these three sorts of movements.

A thing is immovable either when it is wholly incapable of being moved (in the way that a sound is invisible), or when it is moved scarcely at all in a long time or is slow in starting to be moved, that is, when it is said to be difficult to move; or when it is naturally moved and is capable of being so but is not moved either when, where, or how it should in accord with its nature be moved. Among the immovables, the last is the only one I call precisely "at rest"; for rest is contrary to movement, so that it must be a privation in what is receptive of movement.

It is evident from what has been said, then, what movement is, what rest is, and how many sorts of changes and what sorts of movements there are.

5.3
Together, Separate, Making Contact, Intermediate, Successive, Contiguous, Continuous

We next proceed to say what "together [or coincident]" and "separate" are, what "making contact [or touching]" is, what "intermediate" is, and what "successive," "contiguous," and "continuous" are, and to what sorts of things each of these naturally belongs.

Things are said to be together in place when they are in one first place,[233] to be separate when they are in distinct ones, and to be making contact [or touching] when their extremities are together in place.[234]

227[a]7 Since all change is between opposites, however, and these are either contraries or contradictories, and there is no middle term between contradictories, clearly what is intermediate is between contraries. Thus an intermediate involves at least three

233. 209[a]31–[b]1.

234. The Bekker text of what follows is reorganized as indicated.

things. For in a process of change it is the contrary that is the ultimate thing. And an **226b26**
intermediate is what a changing thing—if it changes continuously—arrives at prior 27 | 23
to arriving at the ultimate thing to which, in accord with its nature, it is changing
continuously. And something is moving continuously if it leaves no intervals, or 27
leaves the smallest interval, in the thing—not in the time (for an interval in the time
does not prevent this, and on the other hand immediately after the highest note the
lowest note may sound), but in the thing in which the movement takes place. This is 30
evident in changes with respect to place as well as in other sorts of changes. And to
be contrary in place is to be most distant along a straight line; for the shortest line is
limited, and what is limited is a measure.

A thing is successive when it is after the starting-point in position, in form, or in
some other definite way and when there is nothing of the same kind between it and 35
what it succeeds—I mean, for example, line or lines in the case of a line, units in that **227a1**
of a unit, or houses in that of a house (but there is nothing to prevent something
of some other sort from being in between). For what is successive is successive of
something and is something posterior; for one does not succeed two, nor the first day
of the month the second, but the other way around. What is contiguous is what is 5
successive and making contact.

And continuity is precisely a sort of contiguity. I mean that two things are contin- 10
uous (*suneches*) when the limits of each by which they make contact become one and
the same thing and, as the name signifies, hold together (*sunechêtai*). But continuity
is impossible if these extremities are two. From this definition it is evident that the
continuous is found in those things that by nature become one in virtue of their
making contact. And in whatever way what holds them together is one, so too will 15
the whole be one—for example, by being nailed together, by being glued together, by
contact, or by natural assimilation.

It is also evident that the successive is primary; for things that make contact are
necessarily successive, but not all things that are successive make contact. That is
why succession is found in things, such as numbers, that are prior in account, while
contact is not. And if there is continuity there is necessarily contact, while if there 20
is contact, there need not be continuity; for it is not necessary for the extremities of
things to be one if they are together, but if they are one, it is necessary for them also
to be together. So a natural unity is last in coming to be; for it is necessary for the
extremities to make contact if they are to be naturally unified. But things that are
making contact are not all naturally unified, and in things where there is no contact, 25
in these it is clear that there is no natural unity either.

So, if there is a point and a unit that exist separately, as some people say,[235] it is
impossible for unit and point to be the same; for in points there is contact, while
in units there is only succession. Also, while it is possible for there to be some-
thing intermediate between points (for all lines are intermediate between points), 30

235. Pythagoreans and Platonists. See *Met.* 13.13.

between units there need not be; for there can be nothing intermediate between two and one.

It has now been stated what together and separate are, what making contact is, what intermediate and successive are, what contiguous and continuous are, and the
227b1 sorts of things each of these belongs to.

5.4
What It Is for a Movement to Be One in Kind, in Form, or Unconditionally

A movement is said to be one in many ways; for we say that things are one in many ways. A movement is one in kind in accord with the figures of predication[236] (for any
5 spatial movement is one in kind with any other spatial movement, while alteration is distinct in kind from spatial movement). It is one in form when it is one in kind and is in an indivisible form. For example, there are differences of color (therefore turning dark and turning pale are distinct in form; but be that as it may, every turning pale will be the same in form with every other turning pale and every turning dark
10 with every other turning dark), while of paleness there are not. That is why any turning pale is one in form with any other turning pale. If, however, there is a kind that is at the same time a form, it is clear that the movement will then in a way be one in form, but will not be unconditionally one in form—for example, learning, if scientific knowledge is, on the one hand, a form of supposition, and, on the other, the kind of the sciences.

But one might raise a puzzle as to whether the movement is one in form, when
15 the same thing changes from the same to the same—for example, when one point changes again and again from a particular place to the same particular place. If it is, then circular spatial movement and rectilinear spatial movement will be the same in form, as will rolling and walking. But was it not determined that the movement is distinct in form if what it occurs in is distinct in form, and are not the circular and
20 the rectilinear distinct in form? In kind, then, and in form, a movement is one in this way.

A movement is unconditionally one, on the other hand, when it is one in substance and in number. And what sort of movement this is will be clear from the following distinctions. For there are three things that we speak of in connection with movement: the thing, what it is in, and when. I mean that there must be something that is in movement (for example, a human or gold), and it must be moving in
25 something (for example, in a place or in an affection), and at some time; for all movement occurs in time. Among these three, being one in kind or in form depends on the thing in which the movement occurs being one, being contiguous depends

236. I.e., the categories (225b5–9).

on time, while being unconditionally one depends on all three. And indeed that in which must be one and indivisible, as the form [of movement] is, and the when (the time) must be one and without intermission, and what is in movement must be one, but neither coincidentally (like the pale turning dark or Coriscus walking—Coriscus and the pale are one, but coincidentally) nor in virtue of something common; for two human beings might be being cured at the same time with the same curative process—for example, from eye disease; yes, but this movement is not [unconditionally] one, but one in form. As for Socrates undergoing an alteration that is the same in form at one time and then again at another, if it is possible for what passed away to come to be again while remaining one in number, then this alteration will also be one, if not, it will be the same [in form], but not one.

There is another puzzle much the same as this, as to whether health, and, in general, the states and affections of bodies, are one in substance; for the things that have them are manifestly in movement and flux. If, then, a person's health at daybreak and his health now are one and the same, why should it not also be one and the same as the health he recovers again after an interval? In fact, the same argument applies [to states and activities], except for this difference, that if [the states] are two, it follows because of this that the activities must also be two in number (for an activity that is one in number belongs to a state that is one in number), while if the state is one, perhaps this would seem not yet to be enough for the activity also to be one (for when someone stops walking, the walking no longer exists, but when he is walking again, it will exist again). In any case, if the health is one and the same, it must be possible for what is one and the same to pass away and exist many times over. The puzzles, however, lie outside our present investigation.

But since every movement is continuous, a movement that is unconditionally one must (if indeed every movement is divisible) be continuous, and, if continuous, then also one. For not every movement could be continuous with every other movement, any more than a random thing can be continuous with any other random thing, but rather those in which the extremities are one. Some things have no extremities at all, while those of others are distinct in form and are homonyms; for how could the extremity of a line and of taking a walk make contact and become one? Movements that are not the same in form or in kind may, it is true, be contiguous (for after running someone might immediately fall ill with a fever), and in a torch-race, for example, we have contiguous but not continuous spatial movement. For what are continuous was posited[237] to be those things whose extremities are one. So movements are contiguous and successive in virtue of the time being continuous, but there can be continuity[238] only in virtue of the movements themselves being continuous, and this is when extremities of both become one. That is why it is necessary for a movement that is unconditionally continuous and one to be the

30 **228^{a}1** 5 10 15 20 25 30 **228^{b}1**

237. 227^{a}10–12.
238. Reading συνεχὲς.

same in form, of one thing, and in one time. In one time in order that there may be no intermediate interval of immobility (for during such an interval there must be rest, and a movement is many and not one if it includes an intermediate interval of rest, so that if a movement is divided by a stop, it is neither one nor continuous; and it is divided, if there is an intermediate interval of [rest] time). But of a movement that is not one in form (even if the time is not intermittent), although the time is one, the movement is distinct in form, [and so is not one]; for a movement that is one must also be one in form, though it is not necessary for a movement that is one in form to be unconditionally one. What it is for a movement to be unconditionally one has now been stated.

Further, a movement is also said to be one when it is complete, whether in kind, in form, or in substance, and, just as in the other cases, completeness and wholeness belong to what is one. Sometimes, though, even an incomplete movement is said to be one, but only if it is continuous.

Further, a movement is said to be one in a way distinct from those just mentioned when it is regular. For an irregular movement seems in a way not to be one movement, while a regular one does seem so, as a rectilinear one does; for an irregular one is divisible [into dissimilar parts]. The difference, though, would seem to be one of the more and less. In the case of every sort of movement, however, there may be regularity and irregularity. For a thing may alter in a regular way, and move spatially in a regular path (for example, in a circle or in a straight line), and it is the same with regard to increase and decrease. And irregularity is sometimes a differentiation in the path of the movement (for a movement cannot be regular if its path is an irregular magnitude—for example, a broken line, a spiral, or any other magnitude that is not such that any random part fits onto any other random part). Sometimes it lies neither in the place[239] nor in the time nor in that to which, but in the manner. For sometimes the movement is differentiated by fastness and slowness; for if its speed remains the same, it is regular, but if it does not, it is irregular. That is why fast and slow are neither form nor differences of movement, because they follow along with all movements, [including] the ones that differ in form. So heaviness and lightness, when they are toward the same thing, are not forms or differences either—for example, of earth in relation to itself, or of fire in relation to itself. Irregular movement, then, while it is one in virtue of being continuous,
229a1 is less so, as is precisely the case with spatial movement in a broken line. And what is less so always involves an admixture of the contrary. But if every movement that is one admits of being both regular and irregular, movements that are contiguous but not the same in form cannot be one and continuous; for how could a movement composed of an alteration and a spatial movement be regular? For if a movement is to be regular, it must fit together.

239. Reading ὁτὲ . . . τῷ ποῦ.

5.5
Contrariety of Movement

Further, we must determine what sorts of movements are contrary to each other, and the same way with rest. And we must determine first whether contrary movements are: from the same thing and to the same thing (for example, one from health and one to health), as coming to be and passing away seem to be; from contraries (for example, one from health and one from disease); to contraries (for example, one to health and one to disease); from a contrary to its contrary (for example, one from health and one to disease); or from a contrary to its contrary and from the latter contrary to the former (for example, one from health to disease and one from disease to health). For movements must be contrary to each other in one or more of these ways; for there is no other way in which they can be opposed.

Movements from a contrary to its contrary (for example, one from health and one to disease) are not contrary movements; for they are one and the same. Yet the being for them is not the same, just as changing from health is not the same as changing to disease. Nor are movements from a contrary, and from *its* contrary, contrary movements; for a movement from a contrary is at the same time a movement to a contrary or to an intermediate (but about this we will speak later[240]). Besides, changing to a contrary rather than from a contrary would seem to be a cause of the contrariety of movements; for the latter is the loss, the former the gain, of contrariety. Also, each movement is said to be what it changes to rather than what it changes from—for example, movement to health we call "becoming healthy," movement to disease "becoming sick."

We are left, then, with movements to contraries and movements from contraries to their contraries. Perhaps it happens that movements to contraries are at the same time movements from contraries, but presumably their being is not the same (I mean that a movement to health is not the same as a movement from disease and a movement from health is not the same as a movement to disease).

Since, though, a change differs from a movement (for movement is change from an underlying subject to an underlying subject), it follows that contrary movements are movements from a contrary to its contrary and from the latter contrary to the former—for example, one from health to disease and one from disease to health. But **$229^{b}1$** it is clear from induction too what sorts of things seem to be contraries; for becoming sick seems contrary to becoming healthy, and learning seems contrary to being led, not through one's own agency, into error (for these are to their contraries; for, as with scientific knowledge, it is possible to acquire error either through one's own agency or through that of another). Also, upward spatial movement and downward spatial movement (for these seem to be contraries with respect to length), that to the right

240. $229^{b}14–21$.

and that to the left (for these seem to be contraries with respect to breadth), and forward and backward (for these too are contraries).

As for what is only to a contrary, it is not a movement but a change—for example, becoming pale but not from something. And in those cases in which there is no contrary, it is the change from the same thing and the change to the same thing that are contraries. That is why coming to be is contrary to passing away, and losing to gaining. These are changes, but they are not movements.

And those movements where there is an intermediate, movements to it must be posited as in a way to a contrary; for the intermediate serves as a contrary for the movement, in whichever direction the change may be—for example, one from gray to white is in a way from black, one from white to gray is in a way to black, and one from black to gray is in a way to white; for in relation to each contrary the intermediate is said to be in a way the other contrary, as was also stated previously.[241]

One movement is contrary to another movement, then, in the following way: when one is from a contrary to its contrary and the other is from the latter contrary to the former.

5.6
Contrariety of Movement and Rest

Since movement seems to have as a contrary not only movement but also rest, we must make some determinations about this. For, unconditionally, a movement is contrary to a movement, while rest too is in fact opposed to it (for it is privation of movement, and the privation of something too is in a way said to be its contrary), and rest of a sort to movement of that sort—for example, rest with respect to place to movement with respect to place. But this, as things stands, is said too simply; for is it movement from it or movement to it that is opposed to remaining at a particular place?

It is surely clear that since movement involves two underlying subjects, what remaining at one of these is opposed to is the movement from it to its contrary, while what remaining at its contrary is opposed to is movement from that to it. At the same time, these two are also contrary to each other; for in fact it would be absurd if there were contrary movements, but there were not opposed states of rest. But these **230a1** are in contraries—for example, rest in health is contrary to rest in disease (but is also opposed to the movement from health to disease; for it would be absurd for it to be opposed to the movement from disease to health—for movement to what a thing is at rest in is rather a coming to rest, at any rate, to the extent that it happens at the

241. 224b30–35.

same time as the movement[242]—but it must be either this movement or the other one); for rest in paleness is not contrary to rest in health.

But for things that have no contraries, of which[243] there is a contrary change from the thing to the thing that is not a movement (for example, the change from being to not being[244]), there is[245] no remaining [as or where they are], although there is absence of change. And if there is some underlying subject, absence of change in its being would be contrary to absence of change in its non-being. But if there is not something that is in a state of non-being, one might raise a puzzle as to what it is that is contrary to absence of change in a thing's being, and whether it is rest. If it is, then either not every state of rest is contrary to a movement or else coming to be and passing away are movements. It is clear, therefore, that we must not say that this absence of change is [a state of] rest, if these are not movements, but that it is similar to it and is absence of change. And its contrary is either nothing at all, either absence of change in the thing's non-being, or the passing away of the thing; for its passing away is change from it and its coming to be is change to it.

One might raise a puzzle as to why it is that while in a change with respect to place both remaining in it and moving may be in accord with nature or contrary to it, in the others this is not so—for example, alteration is in some cases in accord with nature and in others contrary to nature (for becoming healthy is no more in accord with nature or contrary to nature than becoming sick, nor turning pale than turning dark). It is the same way in the case of increase and decrease (for these are not contrary to each other in the sense that one is by nature and the other contrary to nature, nor is one increase contrary to another in this sense). And the same argument applies in the case of coming to be and passing away; for it is not the case that coming to be is in accord with nature and passing away contrary to nature (for growing old is in accord with nature), nor, in coming to be, do we see one case in accord with nature and in another contrary to nature.

Or if what is by force is contrary to nature, is passing away by force contrary to nature and as such contrary to passing away in accord with nature? Are there, then, also some comings to be that are by force and not allotted, which are as such contrary to those that are in accord with nature, as well as increases and decreases by force—for example, the rapid growth to maturity due to luxury, and the rapid ripening of seeds, even when not closed up? And how is it in the case of alterations? Or is it the same? For some might be by force, while others are natural—for example, those patients who get rid of their fever not during the days of the crisis and those who do so during the days of the crisis; the first lot alter contrary to nature, the second in accord with nature. But, it may be objected, we will then have passings away that are contrary to each other, not to comings to be. And what exactly is there to prevent their being in

242. Reading ᾗ̔.
243. Reading ὧ̔ν.
244. Reading εἰς τὸ μὴ ὄν.
245. Omitting καὶ.

a way so? For in fact if one is pleasant and the other painful it would. So one passing away will be contrary to another not unconditionally, but insofar as one is of this sort and the other of that sort.

In general, movements and states of rest are contraries in the way we just described—for example, movement upward and rest up above are contrary to movement downward and rest down below; for up and down are contraries belonging to place. And as for the spatial movements, the one that is by nature upward is that of fire, the one by nature downward is that of earth, and the spatial movements of these are contraries. In the case of fire, spatial movement upward is by nature, while the one downward is contrary to nature. And the one that is in accord with nature for it is certainly contrary to the one that is contrary to nature. And states of remaining are similar; for remaining up above is contrary to movement from up above downward, and to earth this remaining occurs against nature and this movement in accord with nature. So the remaining that is contrary to movement is the remaining contrary to the nature of the thing that is contrary to the movement that is in accord with its nature; for in fact its movement contrary to its nature is likewise contrary to it; for one of its movements will be in accord with nature, the upward or the downward, the other contrary to nature.

There is a puzzle as to whether there is a coming to be of every state of rest that is not eternal, and if it is a coming to a stop. If so, then there must be a coming to be of what is remaining contrary to nature—for example, a coming to be of earth's remaining up above. Therefore, at the time that it was by force in spatial movement upward, it was coming to a stop. But what is coming to a stop [in accord with nature] seems to be in spatial movement that is always faster, while with what is in spatial movement by force it seems to be the contrary. Without coming to be at rest, therefore, it will be at rest. Further, a thing's coming to a stop seems to be wholly the same as its being in spatial movement to its own place, or to occur at the same time as it.

There is also a puzzle as to whether remaining in a particular place is contrary to movement from that place; for when a thing is in the process of moving from this and leaving it behind, what it is leaving behind still seems to belong to it, so that if a state of rest is itself contrary to the process of moving from there to its contrary, then contraries will belong to the thing at the same time. But is the thing somehow at rest only if it still remains [as or where it was]? And, in general, is a part of the thing that is in movement in that initial place, while another part is at the one to which it is changing? That is why what is contrary to a movement is a movement rather than a coming to rest.

Concerning movement and rest, then, what way each is one and which are contrary to which, has been stated.

{One might also raise a puzzle, however, about coming to a stop, as to whether in the case of movements that are contrary to nature too there are opposed states of rest. But if this were not so, it would be strange; for a thing may remain [as or where it is] by force (so that there would be something in a non-eternal state of rest without

having come to be in it). But it is clear that this will be so; for just as a thing may be in movement contrary to nature, so too it may be at rest contrary to nature. And since in the case of some things there is movement in accord with nature and contrary to nature (for example, in the case of fire, upward movement is in accord with nature, while downward movement is contrary to nature), is it the latter movement that is contrary to the former one or earth's downward movement (for it spatially moves downward in accord with nature)? Or is it clear that both are, but not in the same way? Instead, earth's downward movement is contrary to fire's upward movement as one movement that is in accord with nature is contrary to another movement that is in accord with nature, while fire's upward movement is contrary to its downward movement as a movement in accord with nature is contrary to a movement contrary to nature. It is the same way in the case of a thing's remaining as or where it is. But perhaps a movement is also opposed in a way to a state of rest.}[246]

BOOK 6

6.1
Every Continuum Consists of Continuous and Divisible Parts (1)

If continuity, making contact, and successive are defined as above,[247] with things being continuous if their extremities are one, making contact if their extremities are together, and successive if there is nothing of the same kind intermediate between them, then a continuous thing cannot be composed of indivisibles—for example, a line of points, if indeed a line is continuous and a point indivisible. For the extremities of a point can neither be one (for there can be no extremity of an indivisible thing as distinct from some other part) nor together (for what has no parts can have no extremities; for the extremity and what it is an extremity of are distinct).

Further, if what is continuous is composed of points, these points must be either continuous or making contact with each other: and the same argument applies in the case of all indivisibles. But in fact they cannot be continuous because of the argument just stated. On the other hand, when one thing makes contact with another, either **231b1** whole makes contact with whole, part with part, or part with whole. But since what is indivisible is without parts, they must make contact as whole with whole. But if they make contact as whole with whole, there will not be a continuous thing. For what is continuous has distinct parts, and may be divided into these, which are then distinct in this way, that is, separated by place.

But then a point cannot succeed a point either, or a now a now, so that a length is composed of points or a time of nows; for things are successive if there is nothing

246. This paragraph is missing from some manuscripts and should perhaps be secluded.
247. 5.3.

of their own kind intermediate between them, while what is intermediate between points is always a line, and between nows [an interval of] time.

Further, each of the two would then be divided into indivisibles, if indeed it is divisible into the parts of which it is composed. But no divisible thing, as we saw, is divisible into things without parts. Nor can there be anything of any other kind that is intermediate. For it will be either indivisible or divisible, and if divisible, either into indivisibles or into things that are always divisible, in which case it will be continuous.

But it is evident too that everything that is continuous is divisible into things that are always divisible; for if it will be divisible into indivisibles, there will be an indivisible making contact with an indivisible; for the extremities of things that are continuous with each other are one and make contact.

The same argument applies to magnitude, time, and movement: either all of these are composed of indivisibles and are divisible into indivisibles, or none are. This is clear from the following. For if a magnitude is composed of indivisibles, the movement along that magnitude will also be composed of an equal number of indivisible movements—for example, if the magnitude ABC is composed of the indivisibles A, B, C, each corresponding part of the movement DEF of O traversing ABC is indivisible. If, then, where there is movement there must be something in movement, and where there is something in movement there must be movement, then what is being moved will also be composed of indivisibles. O, then, traversed A with the movement D, B with the movement E, and similarly C with the movement F. What is in movement from one place to another cannot at the same time be moving and have moved to where it was moving when it was moving (for example, if someone[248] is taking a walk to Thebes, he cannot at the same time be taking a walk to Thebes and have taken a walk to Thebes). And, as we saw, O traverses A, which is without parts, in virtue of the presence of movement D. So, if O passed through A after being in the process of traversing it, then its movement must be divisible (for at the time O was in the process of traversing, it was neither at rest nor had passed through but was in the intermediate). On the other hand, if at the same time O is traversing and has traversed, then what is taking a walk will, at the time it is taking a walk, have taken the walk, and will be there—that is, it will have moved to the place to which it is moving. And if a thing is traversing the whole of ABC, and its movement is the movements D, E, and F, and if it is not in movement at all in A, which is without parts, but has moved in it, then its movement will not be composed of movements but of instantaneous movements, that is, it will occur in virtue of a thing's having moved without being in movement; for it has traversed A without traversing it. So it will be possible for a thing to have taken a walk without ever walking; for it will have taken a walk in A without taking a walk in it.

248. Reading τις.

If, then, everything must be either at rest or in movement, and O is at rest in each of A, B, and C, it follows that a thing can be continuously at rest and at the same time in movement. For, as we saw, O is in movement in the whole of ABC and at rest in any part of it, and so in the whole. Also, if the indivisibles that compose DEF are movements, it would be possible for a thing in which movement is present not to be in movement but at rest, while if they are not movements, it would be possible for a movement not to be composed of movements.

And if length and movement are indivisible, it is likewise necessary for time too to be so, that is, to be composed of indivisible nows; for if every [length or movement] is divisible, and what is traveling with equal speed will traverse a smaller length in less time, then the time will be divisible too. And if the time in which a thing is in spatial movement through A is divisible, A will be divisible too.

6.2
Every Continuum Consists of Continuous and Divisible Parts (2)

Since every magnitude is divisible into magnitudes (for we have proved[249] that it is impossible for anything that is continuous to be composed of indivisibles, and every magnitude is continuous), it necessarily follows that the faster of two things traverses a greater magnitude in an equal time, an equal magnitude in less time, and a greater magnitude in less time, which is just the way faster is defined by some thinkers.

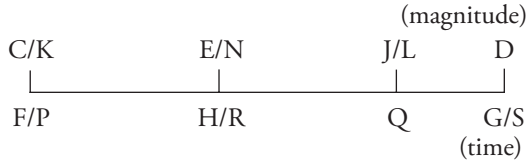

Fig. 1

For let A be faster than B. Since, therefore, of two things, the one that changes earlier is faster, in the time in which A has changed from C to D (for example, the time FG), during that time B will not yet have arrived at D but will fall short of it, so that in an equal time A will traverse a greater magnitude [Fig. 1]. But then it will also traverse a greater one in less time; for in the time it takes A to arrive at D, B, being the slower, has arrived at E. Then since A takes the whole time FG to arrive at D, it will have **232b1** arrived at E in less time than that, let us say in FH. On the one hand, then, CJ, which A has traversed, is greater than CE, and, on the other hand, the time FH is less than the whole time FG, so that A traverses a greater magnitude than B in less time.

It is also evident from this that the faster will traverse an equal magnitude in less time than the slower. For since it traverses a greater magnitude in less time than the

249. 6.1.

slower, and since taken by itself it traverses a greater magnitude in more time than it does a lesser, for example, KL[250] in more time than KN, the time PQ in which it traverses KL will be more than the time PR in which it traverses KN. So, if the time PQ is less than the time PS taken by the slower to traverse KL, the time PR will also be less than the time PS; for PR is less than PQ, and what is less than what is less than a thing is itself less than the latter. So the faster will traverse an equal magnitude in less time than the slower.

Further, since everything must move in a time that is equal to, less than, or more than that of something else, and what moves in more time is slower, what moves in an equal time is of equal speed, and since the faster is neither of equal speed nor slower, then what is faster will move in a time that is neither equal nor more. It remains, then, that it moves in less time. So it is necessary again that the faster traverse an equal magnitude in less time than the slower.

Since every movement is in time and every time is one in which something can move, and since everything that is in movement may be moving faster or slower, in every time there may be faster or slower movement. This being so, it is also necessary for time to be continuous. By "continuous" I mean what is divisible into things that are always divisible. For if this is what continuity is assumed to be, then time must be continuous. For since it has been proved that the faster will traverse an equal magnitude in less time [than the slower], let A be faster and B slower, and let the slower traverse the magnitude CD in time FG [Fig. 2].

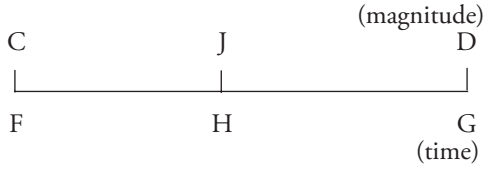

Fig. 2

It is clear, therefore, that the faster will traverse the same magnitude in less time than this. And let it have moved in the time FH. Again, since the faster has traversed the whole of CD in time FH, the slower will in the same time traverse a lesser magnitude, **233a1** and let this be CJ. And since B, the slower, has traversed CJ in the time FH, the faster will traverse it in less time, so that the time FH will again be divided. And if it is divided, the magnitude CJ will also be divided, and in the same ratio. But if the magnitude is divided, so too is the time. And this will always be so if we take the slower after the faster and the faster after the slower, and make use of the same demonstration at each stage; for the faster will divide the time and the slower the length. If, then, this conversion always holds true, and at every turn of the conversion there is a division, it is evident that all time must be continuous. And at the same

250. The reason for the change in notation is unclear.

time it is clear that every magnitude is also continuous; for time and magnitude are divided by divisions that are the same and equal.

Further, it is evident on the basis of the arguments that are customarily stated that if indeed time is continuous, magnitude is continuous too, if indeed in half the time a thing traverses half the distance, and, in general, if in less time it traverses less; for the divisions of the time and of the magnitude will be the same. And if either one of these is unlimited, so is the other, and the one is unlimited in the same way as the other, and the other as the one—for example, if time is unlimited with respect to its extremities, length too is so with respect to its extremities; if with respect to division, length too is so with respect to division; and if with respect to both, magnitude is also so with respect to both.

That is why Zeno's argument[251] is false when it assumes that it is impossible to traverse unlimited things or to touch unlimited things each by each in a limited time. For there are two ways in which length, time, and, in general, anything continuous are said to be unlimited: with respect to division or with respect to their extremities. Therefore, while it is not possible in a limited time to make contact with things that are unlimited in quantity, it is possible if they are unlimited with respect to division; and in fact time itself is unlimited in this way. So it is in an unlimited time and not in a limited one that traversing the unlimited takes place, and contact with things that are unlimited is made by unlimited times, not by limited ones.

Neither, indeed, can an unlimited magnitude be traversed in a limited time, nor a limited one in an unlimited time. Instead, if the time is unlimited, the magnitude will also be unlimited, and if the magnitude is unlimited, the time will be too. For let AB be a limited magnitude, C an unlimited time, and let a limited interval CD of the time [C] be taken. In this interval a thing will traverse a certain segment of the magnitude, and let BE be the segment thus traversed. And this will either measure AB exactly, fall short of it, or exceed it. It makes no difference, in fact, which it is; for if a magnitude that is equal to BE will always be traversed in an equal time, and BE measures the whole magnitude AB, then the whole time taken to traverse AB will be limited; for it will be divided into equal [parts] as the magnitude also is.[252]

Further, if not every magnitude is traversed in an unlimited time, but it is possible to traverse some magnitude—for example, BE—in a limited time, and if this BE measures the whole, and if an equal magnitude is traversed in an equal time, it follows that the time will be limited as well. And it is evident that BE will not be traversed in an unlimited time, if the time is taken to be limited in one of the two directions;[253] for as a part of AB is traversed in less time [than the whole], this time must be limited, since a limit—at any rate in one direction—exists. And if the length is unlimited and the time limited, the demonstration will be the same.

251. $239^{b}11–13$.
252. Reading ὡς καὶ τὸ μέγεθος.
253. Reading ἐπὶ θάτερον.

It is evident, then, from what has been said that neither a line, a plane, nor, in general, anything continuous can be indivisible, not only because of what has just been said, but also because otherwise the indivisible will turn out to be divisible. For since in every interval of time there may be faster and slower movement, and the faster traverses a greater length in an equal time,[254] it is possible for it to traverse a length that is twice, or one and a half times, as great as that traversed by the slower, for this may be the ratio of their respective speeds. Let the faster, then, traverse in the same time a magnitude that is one and a half times that traversed by the slower, and let the magnitude traversed by the faster be divided into three indivisible parts AB, BC, and CD, and that traversed by the slower into the two EF and FG. Then, the time will also be divided into three indivisible parts; for an equal magnitude will be traversed in an equal time. Let the time be divided into JK, LK, and LM [Fig. 3]. Again, since the slower has traversed EFG, the time will also be divided into two.

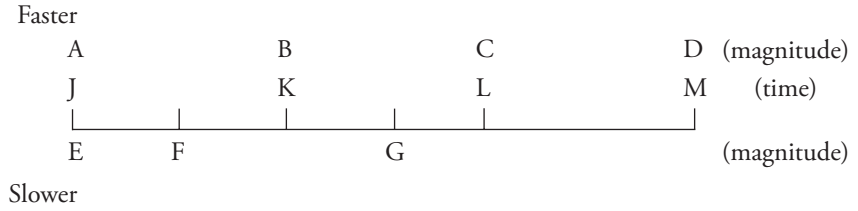

Fig. 3

Therefore, the indivisible will be divided, and what is without parts will be traversed not in an indivisible but in a greater time.

It is evident, then, that nothing continuous is without parts.

6.3
The Now Is Indivisible and Nothing Is in Movement or at Rest in It

It is also necessary for the now—said not with reference to something else, but intrinsic and primary—to be indivisible, and as such to be present in every [interval of] time. For there is an extremity of the past (no part of the future lying on this side of it), and again one of the future (no part of the past lying on this side of it). It, then, we have said,[255] is a limit of both. And if it is proved to be such intrinsically[256] and [for the two limits] to be the same, it will at once also be evident that it is indivisible.

It is necessary for the now that is the extremity of both times to be the same; for if they were distinct, the one could not be successive with the other, because nothing

254. Omitting δὲ.
255. 222ᵃ12. Reading ἔφαμεν.
256. Retaining καθ' αὑτὸ.

continuous can be composed of things without parts, while if the one is separate from the other, there will be a time intermediate between them; for everything continuous is such that there is something synonymous intermediate between its limits. But then if the intermediate thing is time, it will be divisible; for all time has been proved[257] to be divisible. So the now will be divisible. But if the now is divisible, some part of the past will be in the future and some part of the future in the past; for that at which it would be divided is what will determine what is past and what is future time. At the same time, the now would not be something intrinsic, but with reference to something else;[258] for the division will not be intrinsic. In addition, part of the now will be in the past and part in the future, and it will not always be the same one that is past or future. Indeed, the now will not be the same either; for the time is divisible at many points. So, if these features cannot belong to the now, the same now must be in each of the two times it divides. But then, if it is the same, it is evident that it is also indivisible; for if it is divisible, once again the same things will follow as before.

It is clear from what has been said, therefore, that there is something in time that is indivisible, and this we say is the now.

And that nothing is in movement in the now is evident from the following. For if this is possible, then it is possible for there to be faster and slower movement in the now. Let N, then, be the now, and let the faster have moved a distance AC in it. Then the slower will in the same now move a distance less than AC—let it be AB. But since the slower moved the distance AB in the whole now N, the faster will move it in less time, so that the now N will be divided. But we took it to be indivisible. There is not, then, anything that is in movement in the now.

But then nothing is at rest in the now either; for what is at rest, we have said,[259] is what naturally moves but is not in movement when, where, or in the way it would naturally be so. So, since nothing is naturally in movement in the now, it is clear that nothing is at rest in it either.

Further, if the now is the same in both of the times [it divides], and it is possible for a thing to be in movement throughout the whole of one time and at rest throughout the whole of the other, and if what is in movement throughout the whole of a time will be in movement in any part of it in which it is naturally in movement, and what is at rest will likewise be at rest, then it follows that the same thing will be at the same time at rest and in movement; for both the times have the same extremity: the now.

Further, we say that a thing is at rest when it and its parts are in the same state now as previously. But in the now there is no previously, so there is no being at rest either.

Both the movement of what is in movement, therefore, and the being at rest of what is at rest must be in time.

257. 232^{b}19–233^{a}12.
258. 222^{a}10–24.
259. 226^{b}12–16. Reading ἐλέγομεν.

6.4
Modes of Divisibility

Also, everything that is changing must be divisible. For since every change is from something to something, and when a thing is in what it has changed to, it is no longer changing, and when both it itself and all its parts are in what it changes from it is not[260] changing (for what keeps in the same state, both itself and its parts, is not changing), it is necessary that part of what is changing must be in what it is changing from and part in what it is changing to; for it cannot be in both or in neither of the two. By "what it is changing to" I mean the first one with respect to the change—for example, gray not black, if it is changing from white; for it is not necessary for what is changing to be at either of the extremes. It is evident, then, that everything that is changing will be divisible.

Movement is divisible in two ways. One way is with respect to the time, another is with respect to the movements of the parts of what is in movement—for example, if the whole AC is in movement, its parts AB and BC will also be in movement. Let the movement of the parts, then, be DE for AB and EF for BC. It is necessary, then, for the whole DF to be the movement of AC. For it will be in this movement [DF], if indeed each of its parts is moving with its respective movement (since the one part is not in movement with respect to the movement of the other). So the whole movement is the movement of the whole magnitude.

Further, if every movement is the movement of something, and the whole movement DF is neither the movement of either of the parts (for of the parts it is the respective parts of the movement) nor of anything other than them (for a whole movement is of a whole thing, and the parts of the parts, and the parts of the movement are the movements of AB and BC and nothing else; for, as we saw,[261] a movement that is one cannot be the movement of more than one thing), then the whole movement will be that of the magnitude of ABC.

Further, if the movement of the whole is something else, for example, HI, the movements of each of its parts may be subtracted from it. And these will be equal to DE and EF; for the movement of what is one is one. So, if the whole movement HI is divided into the movements of the parts, HI will be equal to DF. On the other hand, if there is a remainder, for example, JI, this will be a movement of nothing (for it can be the movement neither of the whole nor of the parts, because the movement of what is one is one, nor of anything other than them; for a movement that is continuous must be of things that are continuous), and likewise if there is an excess with respect to the division. So, if this is impossible, it is necessary for the movement HI to be the same as and equal to DF.

260. Reading οὐ.

261. The reference is unclear, but is perhaps to 227b20–228a6.

This, then, is what division of movement with respect to the movement of the parts is. And it must be applicable to everything that is divisible into parts.

Another division is with respect to time; for since every movement is in time, and all time is divisible, and in less time the movement is less, it is necessary for every movement to be divisible with respect to time. But since everything that is in movement is in movement in a certain respect and for a certain time and the movement is of the entire thing, it is necessary for there to be the same divisions of the time, the movement, the being-in-movement, the thing that is in movement, and what the movement is with respect to (although the divisions of what the movement is with respect to are not all alike; rather, those of quantity[262] are intrinsic, those of quality coincidental).

For let the time in which a thing is in movement be A, and the movement B. If, then, in all the time the thing completed the whole movement, in half the time it completed less of it, and, if this time is divided, less of it again, and so on always in the same way. Similarly, if the movement is divisible, the time will also be divisible; for if the whole movement is in all the time, the half is in half the time, and less again in less of it.

And the being-in-movement is also divisible in the same way. For let C be the whole being-in-movement. The being-in-movement, then, that corresponds to half the movement will be less than the whole, and the one that corresponds to half of the half will be less again, and so on always in the same way. And by setting-out the beings-in-movement corresponding to each of the two movements, for example, corresponding to DC and CE,[263] we may also say that the whole being-in-movement will be that with respect to the whole movement (for if some other being-in-movement does so, more than one being-in-movement will correspond to the same movement)—[which can be proved] in the same way as we proved that the movement of a thing is divisible into the movements of its parts; for if we take the beings-in-movement as corresponding to each of the two movements, the whole will be continuous.

The divisibility of the length will also be proved in the same way, as, in general, will be that of everything with respect to which there is change (although some of these are coincidentally divisible, because the thing that is changing is so); for when one is divided all will be divided. So too in the issue of their being limited or unlimited, they will all alike be either one or the other. And in most cases the fact that all the things we looked at were divisible or unlimited followed along with the fact that the thing that is changing is so; for divisibility and unlimitedness belong directly to the thing that is changing. That divisibility does so was proved previously;[264] that unlimitedness does so will be made clear in what follows.[265]

Issues Concerning Change (1)

Since everything that changes changes from something to something, it is necessary for what has changed, at the moment when it has first changed, to be in what it has changed to. For what is changing gets rid of and leaves behind what it is changing from, and leaving behind and changing are either the same or leaving behind follows along with changing. And if leaving behind follows along with changing, having left behind follows along with having changed; for in each pair there is a similar relation between its two members.

Since, then, one sort of change is with respect to contradiction, when a thing has changed from non-being to being, it has left non-being behind. Therefore, it will be in being; for everything must either be or not be. It is evident, then, that in change with respect to contradiction what has changed must be in what it has changed to. And if this holds in this sort of change, it will also hold in the others; for what holds in the case of one sort, holds also in that of the others.

Further, if we take each sort separately it is also evident that this is so, if indeed what has changed must be somewhere or in something. For since it has left behind what it has changed from and must be somewhere, it will be either in what it has changed to or in something other than it. If, then, what has changed to C is in something other than C, for example, B, then it is changing again from B to C; for C was not contiguous to B, for[266] the change is continuous. So what has changed, at the moment when it has changed, is changing to what it is changing to. But this is impossible. Therefore, what has changed must be in what it has changed to. It is also evident, then, that what has come to be, at the moment when it has come to be, will be, and that what has passed away will not be; for what was said applies universally to every sort of change, and is most of all clear in that with respect to contradiction. It is clear, therefore, that what has changed, at the moment when it has first changed, is in what it has changed to.

But the primary [time] in which what has changed has changed must be indivisible. By "primary" I mean that it is not in virtue of some other thing than it that the thing is such-and-such. For let the time AC be divisible, and let it be divided at B. If, then, the thing has changed in AB or again in BC, AC cannot be the primary time in which it has changed. If, on the other hand, it were changing in each (for it must either have changed or be changing in each of them), it would also be changing in the whole AC. But it has [already] changed in AC. And the argument is the same even if the thing is changing in one part and has changed in the other; for then there will be something prior to what is primary. So the time in which the thing has changed must not be divisible. It is also evident, then, that the time in which what has passed away has passed away or in which what has come to be has come to be is indivisible.

266. Reading τῷ B, ἡ γὰρ.

But something is said to be the primary time in which a thing has changed in two ways, on the one hand, when it is the primary one in which the change has been completed (for then it is true to say that it has changed), and, on the other hand, when it is the primary one in which the changing started. What is said to be primary, then, with reference to the end of the change does really exist (for a change admits of being completed, and there is an end of change, and it was proved[267] to be indivisible because it is a limit). But what is said to be primary with reference to the starting-point does not exist at all; for there is no starting-point of a change nor a primary part of the time in which a thing started to change.[268] For let BC be a primary part. It is certainly not indivisible; for otherwise the nows would be contiguous. Further, if the thing is at rest in all of the time AB [immediately preceding BC] (for let it be posited that it is at rest), it is also at rest in B. So, if BC is without parts, the thing will be at rest and have changed at the same time; for it is at rest in B and has changed in C. But, since BC is not without parts, it must be divisible, and the thing must have changed in any part of it whatever; for since BC is divided, if it has changed in neither of the two parts that it is divided into, it has not changed in the whole of it either; while, if it is changing in both, it is also changing in all of it; and if it[269] has changed in one of the two, it has not changed in the whole primarily. So it must have changed in any part of it whatever. It is evident, therefore, that there is no primary time in which it has changed; for the divisions [of time] are unlimited.

Of what has changed, there is also no primary part that has changed. For let DZ be the primary part of DE that has changed; for every changing thing has been proved[270] to be divisible. And let the time in which DF has changed be HI. If, then, DF has changed in the whole time, what[271] has changed in the half will be less than and so prior to DF, and there will be another part again that is prior to this, and another, and so on always in the same way. So of what has changed there will be no primary part that has changed.

It is evident, then, from what has been said that there is no primary part either of what changes or of the time in which it changes.

But with the thing itself that changes, or [better] what a thing changes with respect to, it will no longer be the same way. For three things are mentioned with regard to change: what changes, what it changes in, and what it changes to—for example, the human being, the time, and the pale. The human being and the time are divisible, but in the case of the pale there is another account. Except that they are all indeed coincidentally divisible; for what the pale or the quality coincides with is divisible; since of those that are said to be intrinsically and not coincidentally divisible there will be no primary part that changes—for example, there will be none in magnitudes. For

268. Reading μετέβαλεν.
269. Reading εἰ δ'.
270. 234^{b}10–20.
271. Reading τὸ.

let AC be a magnitude, and let it have moved from A to a primary point B.[272] Then, if AB is indivisible, a thing without parts will be contiguous to a thing without parts, while if it is divisible, there will be something prior to B to which the magnitude has changed, and something else again prior to that, and so on always in the same way, because the process of division can never come to an end. So there will be no primary one to which it has changed. It is likewise, too, in the case of quantitative change; for here too the change is in something continuous.

It is evident, then, that only in movement with respect to quality can there be intrinsic indivisibility.

6.6
Issues Concerning Change (2)

But since everything that changes changes in time, and is said to be changing in time both as changing in a primary time and as doing so with respect to another time (for example, when we say that it changes in a particular year because it changes in a particular day of it), if what changes is changing in a primary time, it must be changing in any part of it whatever. This is clear even from the definition (for "primary" was meant[273] in this way), but it is also evident from the following. Let the primary time, in which what is in movement is in movement, be VQ, and let it be divided at J; for all time is divisible. In the time VJ the thing either is in movement or is not in movement, and likewise in turn in the time JQ. If, then, it is in movement in neither of the two, it will be at rest in the whole (for to be in movement in it when in movement in none of its parts is impossible). But if it is in movement in only one of the two, then VQ cannot be the primary time in which it is in movement; for its movement will be with respect to a time other than VQ. Therefore, it must be in movement in any part whatever of VQ.

Now that this has been proved, it is evident that everything that is in movement must have been in movement previously. For if in the primary time VQ the thing has traversed the magnitude JK, then in half that time a thing that is moving with the same speed and that started its movement at the same time will have traversed half of it. But if this second thing, which is traveling at the same speed, has traversed
237a1 a certain magnitude in a certain time, the first thing must have traversed the same magnitude [in the same time], so that what is in movement must have been in movement previously.

272. Think of AC as a continuous line that has grown in length from A to C (at which point it has the magnitude in question), and suppose that it has done so by first reaching some point B. If AB is indivisible, A and B will both be indivisible, without parts, and contiguous—which is impossible. If AC is divisible, say at X, then AX not AC will be the first part of AB to achieve the magnitude in question, and so on.

273. 235b33–34.

Further, if we say that a thing has moved in all the time VQ—either in the whole of it or, in general, in any part whatever—by taking its extreme now (for it is this that defines it, and what is intermediate between nows is time), it would likewise be said to have moved in the others. But the extremity of the half is a division. So the thing will have moved both in half the time and, in general, in any part of it whatever; for as soon as any division is made there is always a time defined by the nows. If, then, all time is divisible, and what is intermediate between nows is time, everything that is changing must have changed an unlimited number of times.

Further, if what is changing continuously, without having passed away or having ceased changing, must have been changing or have changed in any part of the time whatever, and since it cannot be changing in a now, it must have changed with respect to each of the nows. So, if the nows are unlimited in number, everything that is changing will have changed an unlimited number of times.

And not only must what is changing have changed, but what has changed must also previously have been changing; for everything that has changed from something to something has changed in an interval of time. For let a thing have changed from A to B in a now. Then the now in which it has changed cannot be the same as the one in which it is in A (for otherwise it would be in A and B at the same time); for we have proved previously[274] that what has changed, at the moment when it has changed, is not in what it has changed from. But if it is in another now, there will be an interval of time intermediate [between the two nows]; for, as we saw,[275] nows are not contiguous. Since, then, it has changed in an interval of time, and all time is divisible, in half that interval it must have made another change, and in half the half another again, and so on always in the same way, so that it must have been changing previously.

Further, what has been said is more evident in the case of magnitude, because the magnitude in which what is changing changes is continuous. For let a thing have changed from C to D. Then if CD is indivisible, a thing without parts will be contiguous to a thing without parts. But, since this is impossible, what is intermediate between them must be a magnitude and must be divisible without limit into magnitudes. So it must previously have been changing to the latter. Therefore, everything that has changed must previously have been changing. The same demonstration, indeed, also applies to what is not continuous—for example, in the case of contraries and in that of contradictories; for the time in which the thing has changed may be taken, and then we may state the same argument again. So what has changed must have been changing and what is changing must have changed, and there will be a having changed previous to a changing, and a changing previous to a having changed, and at no time can one be taken as primary. And the cause of this is that no thing

274. $235^{b}6$–13.
275. $218^{a}18$–19, $231^{b}6$–10.

without parts can be contiguous to a thing without parts; for the division is without limit, just as in increasing and decreasing lines.[276]

It is also evident, then, that what has come to be must previously have been coming to be, and that what is coming to be must previously have come to be (that is, the ones that are divisible and continuous[277]), although it is not always of what the thing is coming to be that this holds, but sometimes it is something else, for example, some part of it, like the foundation of a house. Likewise in the case of what is passing away and what has passed away; for in what comes to be and in what passes away something unlimited is immediately present precisely because they are continuous. And a thing can neither be coming to be without having come to be nor have come to be without coming to be, and likewise too in the case of passing away and having passed away; for having passed away is always previous to passing away, and passing away to having passed away.

It is evident, then, that what has come to be must previously have been coming to be, and that what is coming to be must previously have come to be; for every magnitude and every interval of time is divisible without limit.

So in whatever [time or magnitude] a thing may be, it cannot be in it as in a primary one.

6.7
The Limitedness or Unlimitedness of Movement, Magnitude, and of What Is Moved

Since everything in movement is moving in time, and in a longer time covers a greater magnitude, it cannot cover a limited magnitude in an unlimited time, if it is not always moving in the same movement and in some iteration of it,[278] but rather covers all of the magnitude in all of the time.

It is clear that if a thing is moving with equal speed, it must cover a limited magnitude in a limited time (for if a part is taken that will measure the whole, the thing will have covered the whole magnitude in as many equal intervals as there are parts of the movement, so since the parts are limited, both each individually in magnitude and all collectively in number, the whole time will also be limited; for it will be so-and-so

276. Bisect a line AE at B, BD at C, and CE at D:

The result is an increasing series of lines (AB, AC, AD, . . .), each of which is longer than its predecessor, and a decreasing series (AB, BC, CD, . . .), each of which is shorter than its predecessor.

277. *Met.* 1027a29–30.

278. As in unlimited movement in a circle.

many times so-and-so much, equal to the time of a part multiplied by the number of the parts).

And if the speed is not equal it makes no difference. For let AC be a finite extension which the thing has traversed in an unlimited time, and let the unlimited time be DE. If, then, one part of the extension must have been covered before another part **238^{a}1**
(and this is clear, because in the earlier and in the later part of the time a distinct part has been covered; for in a longer time a distinct part will always have been covered, whether the thing changes with equal speed or not with equal speed, and whether the speed of the movement increases, diminishes, or remains the same, this is no less so), let us then take AB, a part of the extension AC, that will measure AC. This part, then, was traversed in a certain limited part of the unlimited time; for it cannot be in an unlimited one; for the whole movement [AC] took an unlimited one. And if I again then take a distinct part equal to AB, it too must have been traversed in a limited time; for it was the whole movement that took an unlimited one. And if I go on taking parts in this way, then, since no part of what is unlimited will measure what is unlimited (for the unlimited cannot be composed of a limited number of parts, whether equal or unequal, because equal or unequal parts that are limited in number and magnitude will be measured by some one unit, and so, whether they are equal or unequal, will nonetheless be definite in magnitude), and since the limited extension AC is measured by so-and-so many times AB, AC would be traversed in a limited time. And it is the same way with coming to rest. So it is impossible for one and the same thing to be always coming to be or always passing away.

The same argument will also prove that in a limited time what moves cannot be either in an unlimited movement or in an unlimited coming to rest, whether it is moving with a regular or an irregular movement. For if a certain part is taken that will measure the whole time, in it some quantity of the magnitude will be traversed and not the whole (for the whole will be traversed in all of the time), and again in another equal part another quantity, and likewise in each part, whether equal or unequal to the one at the start (for this makes no difference, provided only that each is limited); for it is clear that when the time is exhausted, the unlimited magnitude will not be, since the process of subtraction is limited both in the quantity [of each subtraction] and in the number of subtractions. So the unlimited magnitude will not be traversed in a limited time. And it makes no difference whether the magnitude is unlimited in one of the two directions or in both; for the argument will be the same.

These things having been demonstrated, it is evident that neither can a limited magnitude traverse an unlimited magnitude in a limited time, due to the same cause; for in part of the time it will traverse a limited magnitude, and in each part it will do likewise, so that in the whole time it will traverse a limited magnitude.

And since a limited magnitude will not traverse an unlimited one in a limited time, it is clear that neither will an unlimited one traverse a limited one; for if the **238^{b}1**
unlimited one can traverse the limited one, the limited one must also traverse the unlimited one. For it makes no difference which of the two is the one in movement;

for either way the limited traverses the unlimited. For when the unlimited magnitude A is in movement, a part of it—for example, CD—will traverse the limited magnitude B, and then another, and then another, and so on always in the same way. So the unlimited magnitude A will have traversed the limited magnitude B at the same time as the limited magnitude B will have traversed the unlimited A; for perhaps there is no other way possible for the unlimited one to have traversed the limited one than by the limited one traversing the unlimited one, either by being in spatial movement over it or by measuring it. So since this is impossible, the unlimited one cannot traverse the limited one.

But then neither does the unlimited one traverse the unlimited one in a limited time; for if it traverses the unlimited one, it will also traverse the limited one; for the limited one is contained in the unlimited one. Further, by taking the time, the demonstration will be the same.

Since in a limited time, then, the limited one does not traverse the unlimited one, nor the unlimited the limited, nor the unlimited the unlimited, it is evident that neither will there be unlimited movement in a limited time; for what difference does it make whether it is the movement or the magnitude that we posit as being unlimited? For if either of the two is unlimited, the other must be so as well; for all spatial movement is in a place.

6.8
Rest and Coming to Rest

Since everything that is either naturally in movement or naturally at rest is so when, where, and in the way that is natural, what is coming to a stop, when it is coming to a stop, must be in movement; for if it is not in movement, it is at rest, but it is not possible for what is at rest to be coming to be at rest. This having been demonstrated, it is also evident that coming to a stop must be in time (for what is in movement is in movement in time, and what is coming to a stop was proved to be in movement, so it is necessary for coming to a stop to be in time). Further, what we say is faster or slower is in time, and coming to a stop may be faster or slower.

And what is coming to a stop must be coming to a stop in any part whatever of the primary time in which it is coming to a stop. For if it is coming to a stop in neither of the two parts that the time may be divided into, it will not be doing so in the whole time either, so that what is coming to a stop will not be coming to a stop. On the other hand, if it is coming to a stop in only one of the two parts, then the primary time in which it is coming to a stop will not be the whole time; for it will be coming to a stop with respect to something else—as we also stated previously in the case of what is in movement.

And just as there is no primary time in which what is in movement is in movement, so too there is not one in which what is coming to a stop is coming to a stop;

for neither in the case of being in movement nor in that of coming to a stop is there a primary one. For let AB be the primary time in which a thing is coming to a stop. Then AB cannot be without parts (for there is no movement in what is without parts, because part of it[279] has to have moved, and what is coming to a stop has been proved[280] to be in movement). But then if AB is divisible, the thing is coming to a stop in any part of it whatever; for we have proved previously[281] that it is coming to a stop in any part whatever of the primary time in which it is coming to a stop. Since, then, what a thing is primarily coming to a stop in must be an interval of time, and not something indivisible, and since all time is divisible without limit, there cannot be any primary [interval of] time in which it is coming to a stop. **239ª1**

Nor, then, can there be a primary time in which what is at rest has come to be at rest. For it cannot have come to be at rest in what is without parts, because there cannot be movement in what is indivisible, and what there is being at rest in there can also be being in movement in (for something is at rest, we said,[282] if it can be naturally in movement but is not in movement when—that is, in that time in which—it is natural). Further, we also say that a thing is at rest when it is in the same state now as previously, as judged not by one point but by at least two.[283] So what a thing is at rest in cannot be without parts. But if it is divisible into parts, it would be an interval of time, and the thing will be at rest in any part of it whatever. For this can be proved in the same way as in the previous cases.

So there will be no primary interval of time. And the cause of this is that everything is at rest and in movement in time, and there is no time, magnitude, or, in general, continuous thing that is primary; for all of them are divisible without limit into parts.

And since everything that is in movement is in movement in time and changes from something to something, in that time in which it is moving intrinsically and not in some part of that time, it is impossible then for what is in movement with respect to some particular thing primarily. For to be at rest is for a thing and each of its parts to be in the same state in the same time. For this is the way we speak of a thing as being at rest: when at one now after another both it and its parts can truly be said to be in the same state. But if this is what being at rest is, it is impossible for what is changing to be doing so as a whole with respect to some particular thing in a primary time. For all the time is divisible, so that in one part of it after another it will be true to say that the thing itself and its parts are in the same state. For if it is not so in this way, but only at one now, then the thing will be the same in some certain respect not for an interval of time but in [a now that is] the limit of that time. But though in a now [what is in movement] is always the same with respect to

279. Secluding ἂν.
280. 238ᵇ23–26.
281. 238ᵇ31–36.
282. 226ᵇ12–15.
283. Since all movement and change is from something to at least one other something.

something that remains[284] unchanged, it is nonetheless not at rest; for the thing is
239b1 neither in movement nor at rest in a now. And, though it is true that, in a now, it is not in movement and is the same with respect to a particular thing, it cannot in an interval of time be so with respect to what is[285] at rest; for it then follows that what is in spatial movement is at rest.

6.9
Arguments against the Possibility of Movement

But Zeno argues fallaciously; for he says that if everything is always at rest when it is so with regard to what is equal [to itself], and what is in movement is always like that in a now, then an arrow that is in spatial movement is unmoving. But this is false. For time is not composed of indivisible nows any more than any other magnitude is composed of indivisibles.

Zeno's arguments about movement, which present difficulties to those trying to resolve them, are four in number:

The first states that there is no movement because what is in spatial movement must arrive at the halfway point before it arrives at the end. We went through it previously.[286]

The second is the so-called Achilles. It is as follows. The slowest runner will never be overtaken by the fastest; for the pursuer must first reach the point from which the former started, so that the slower must always be a bit ahead. This argument is in effect the same as that from bisection, though it differs from it in not dividing in half the additional magnitude being taken.[287] The conclusion of the argument, then, is that the slower is not overtaken, but it is reached in the same way as by bisection (for in both cases what follows is that the limit is not reached when the magnitude is divided in a certain way, although there is the additional conclusion that even the famously fastest runner[288] will fail to catch the slowest one), so that the resolution must be the same. And the claim that what is a bit ahead is never overtaken is false; for though at the time it is a bit ahead it is not overtaken, nonetheless it is overtaken if indeed it is granted that it is possible to traverse the limited distance in question.[289]

284. Reading μένον.
285. Reading τὸ.
286. 233a21–31.
287. I.e., the one covered by the slowest runner.
288. Achilles.
289. Achilles' speed is S_a, which is faster than the turtle's speed S_t; the point at which the turtle starts moving is 1. When Achilles reaches 1, Zeno proves that he is S_t/S_a behind, and that when he has traveled $1 + S_t/S_a$, he is S_t^2/S_a^2 behind, and so on. But he has not proved that when Achilles has traversed $S_a/S_a–S_b$ he is still behind, provided it is granted that this limited distance can be traversed in a limited time.

These, then, are two of the arguments. The third, stated just now, is that an arrow in spatial movement is at rest.[290] This results from assuming that time is composed of nows; for, if this is not granted, there will be no deduction.

The fourth argument concerns two rows of bodies in a stadium that are equal in size to each other in opposite directions and in front of other bodies of equal size, one lot starting from the end, the other from the middle, and both moving at equal speed, from which it follows, he thinks, that half of a time is equal to its double. The fallacy in this lies in the claim that an object in spatial movement with an equal speed takes an equal time to pass in front of a moving body as to pass in front of a body of an equal size that is at rest. But this is false. For example, let AA be the bodies of equal volume that are at rest, BB the bodies that start from the middle of the As,[291] equal in number and size to these, and CC the bodies that start from the extremity [of the As], equal in number and size to these, the speed of which is equal to that of the Bs [Fig. 4].

$A_1\ A_2\ A_3\ A_4$

$B_4\ B_3\ B_2\ B_1 \longrightarrow$

$\longleftarrow\ C_1\ C_2\ C_3\ C_4$

Fig. 4

It follows, then, that the first B is at the extremity [A_4] at the same time as the first C, when they are moving past each other. It follows that the first C has passed all the Bs,[292] while the first B has passed half [the As]. So the time is half; for each of the two takes the same time to pass each body. But, at the same time, it follows that the first B has passed all the Cs; for the first C and the first B will be at opposite extremities [of the As] at the same time, because both the first C and the first B are for an equal time in front of each A. The argument, then, is as above, but it proceeds from the falsehood mentioned.[293]

Nor with regard to change to a contradictory will there be anything impossible for us to face—for example, from the argument that if a thing is changing from not white to white but is neither one nor the other, it is therefore neither white nor not white; for if a thing is not wholly in either of the two states, it does not follow that it will not be said to be white or not white; for we say that a thing is white or not white not when the whole of it is such, but when most of its parts or its most controlling parts are: not being in a state is not the same as not being wholly in it. The same holds

290. 239^{b}5–7.
291. Reading τῶν α.
292. Retaining τὰ B.
293. 240^{a}1–4.

in the case of being and in the case of not being, and of the other pairs of contradictories; for while a thing will of necessity be in one or the other of the opposites, it is never wholly in one or wholly in the other.

And this is so again in the case of the circle and the sphere and, in general, of what is in movement within [the place occupied by] itself, and it is argued that it follows that they are at rest; for each of them and its parts will be in the same place for any interval of time, and so will be at rest and in movement at the same time. For, first, the parts are not in the same place for any interval of time, and, second, the whole is also always changing to something else; for the circumference taken from point A is not the same as the one taken from point B, C, or from each of the other points—except in the way that the human and the musical human are the same, because they coincide [Fig. 5].

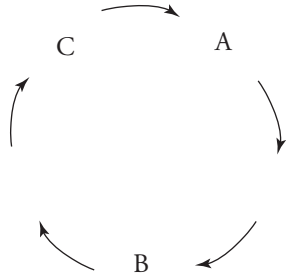

Fig. 5

So the circle is always changing from one [place to another], and will never be at rest. And it is the same way in the case of the sphere and in that of whatever else is in movement within [the place occupied by] itself.

6.10
The Movement of What Is without Parts; No Change Is Unlimited

Having demonstrated these things, we are now in a position to state that what is without parts cannot be in movement except coincidentally—for example, by the movement of the body or magnitude in which it is present, just as what is in a boat may be in movement due to the spatial movement of the boat, or as a part will be in movement due to that of the whole. (By "without parts" I mean what is indivisible with respect to quantity.) For even the movements of the parts that are intrinsic to the parts are distinct from the movements of the parts with respect to the whole. The distinction may be seen most clearly in the case of a [revolving] sphere; for the speeds

of parts near the center, of those near the surface, and of the whole sphere are not the same, implying that their movements are not one.

As we have said, then, what is without parts can be in movement in the way that a man sitting in a boat is in movement when the boat is traveling, but it cannot be so intrinsically. For let it be changing from AB to BC, whether from a magnitude to a magnitude, from a form to a form, or with respect to a contradiction. And let D be the primary time in which it is changing. Then in the time in which it is changing it must be in AB or BC or partly in one and partly in the other; for this, as we saw,[294] is true of everything that is changing. It will not, though, be partly in each of the two; for then it would be divisible into parts. But then neither will it be in BC; for then it will have changed, while it is assumed to be changing. It remains, then, that it is in AB in the time D in which it is changing. Therefore, it will be at rest; for, as we saw,[295] to be in the same state for an interval of time is to be at rest.

So it is not possible for what is without parts to be in movement or, in general, changing; for there is only one way in which such movement would be possible for it, if time was composed of nows; for then in every now it would have moved and changed, so that it would at no time be moving, but at every time have moved. But that this is impossible was already proved previously;[296] for time is not composed of nows, nor a line of points, nor a movement of instantaneous movements; for someone who states this, that it is possible for what is without parts to be in movement, does nothing other than make movement out of things without parts, just as he makes time out of nows, and length out of points.

Further, it is also evident from the following that neither a point nor any other indivisible thing can be in movement. For whatever is in movement cannot traverse a line greater than itself without previously traversing one that is equal to or less than itself. If, then, this is so, it is evident that a point too must first traverse a line equal to or less than itself. But since a point is indivisible, it cannot previously traverse one less than itself. It must, therefore, traverse one equal to itself. So the line will be composed of points; for since at every time the point traverses something equal to itself, it will measure out the whole line. But if this is impossible, it is also impossible for what is indivisible to be in movement.

Further, if everything is in movement in time, but nothing is in movement in a now, and if all time is divisible, then for everything in movement there would be a time less than that in which it traverses a part as great as itself. (For there will be such a time for what is in movement, because everything in movement is so in time, and it was proved previously that all time is divisible.[297]) If, therefore, a point is in

294. 234^{b}10–17.
295. 239^{a}26–29.
296. 237^{a}17–^{b}22.
297. 232^{b}23–233^{a}10.

movement, there must be a certain time less than that in which the point itself[298] has moved. But this is impossible; for in less time it must traverse less. So what is indivisible will be divisible into something less than itself, just as the time is into intervals of time. For there is only one way in which what has no parts and is indivisible would be in movement, if it could be in movement in a now that is indivisible; for the same argument is involved in being in movement in the now as in an indivisible thing being in movement.

No change is unlimited; for every change, both between contradictories and between contraries, is from something to something. So in changes with respect to contradiction, the affirmation or the denial is the limit—for example, in coming to be it is being, in passing away it is not being. And in those between contraries it is the contraries that are the limit; for these are the extremities of the change, and so of all alteration (for alteration is always from certain contraries).

It is likewise with increase and decrease; for the limit of increase is the complete magnitude that is in accord with the nature proper to what is increasing, while the **241b1** limit of decrease is the complete departure of this magnitude.

Spatial movement, on the other hand, is not limited in this way; for it is not always between contraries. But since what is incapable of being cut (I mean, in the sense that it does not admit of being cut; for something is said to be incapable in many ways)—what is incapable of being cut in this sense does not admit of being cut here and now, and, in general, what is incapable of coming to be does not admit of coming to be here and now, and what is incapable of changing does not admit of changing here and now to what it is incapable of changing to. If, then, what is in spatial movement is changing here and now to something, it will have the capacity to have changed to it. So its movement is not unlimited, nor will it be in spatial movement over an unlimited distance; for it cannot traverse it.

It is evident, then, that no change is unlimited in this way: in not being defined by limits. But whether a change, being one and the same, can be such as to be unlimited in time must be investigated.[299] For if the change is not one, perhaps nothing prevents this—for example, if a spatial movement is followed by an alteration, this by an increase, and this again by a coming to be; for in this way there will be forever a movement in time, but not one movement, because there is not one that is composed of all these. So, if it is to be one, no movement admits of being unlimited in time except one; and this is the spatial movement in a circle.

BOOK 7[300]

7.1
The Need for a Primary Mover

Everything that is in movement must be moved by something; for if it does not have the starting-point of movement within itself, it is evident that it is moved by something else (for what causes the movement will be some other thing); but if it does have the starting-point within itself, let AB be what is in movement intrinsically and not because some part of it is in movement. First, then, to assume that AB, because it is in movement as a whole and is not moved by anything external to itself, is therefore moved by itself is the same as, if JK is moving KL and is itself in movement, one were to assume that JL is not moved by anything, because it is not evident which part is the mover and which the moved.

Next, it is not necessary for what is not moved by anything to cease being in movement because something else is at rest, but, if a thing is at rest due to something else's having ceased moving, then it is necessary for it to be in movement due to something.

I say this because[301] if this is accepted, everything that is in movement must be moved by something. For, since AB has been taken to be in movement, it must be divisible (for everything in movement is divisible). Let it be divided, then, at C. Then when CB is not in movement, AB will not be in movement; for if AB were to be in movement, it is clear that AC would be in movement when CB is at rest, so that AB will not be in movement intrinsically and primarily. But it was assumed to be in movement intrinsically and primarily. Therefore, if CB is not in movement, AB must be at rest. But it was agreed that what is at rest if something else is not in movement must be moved by something, so that it is necessary for everything that is in movement to be moved by something. For what is in movement will always be divisible, and if a part of it is not in movement, the whole too must be at rest.

But since everything that is in movement must be moved by something, if it should happen that something that is in spatial movement is moved by something else that is in movement, and the latter is moved by something else again that is in movement, and that one by something else, and so on always in the same way, it is necessary for there to be some primary mover, and the series does not go on without limit. For suppose this is not so, suppose it does go on without limit. Then, let A

300. 7.1–3 exist in two versions, α and β (hence the non-standard Bekker page numbers). α is translated here with a translation of the β text of 7.3 appended at the end of the *Physics*. Books 5, 6, and 8 form a unified discussion, parts of which are often referred to as—or as included in—"our first accounts concerned with movement." Book 7 interrupts this sequence, suggesting that it may have been incorporated at a later date.

301. Reading γὰρ.

be moved by B, B by C, C by D, and always the next one by the next one. Since, then, it is taken as a hypothesis that the mover moves by being in movement, it is necessary for the movement of the moved and the movement of the mover to occur at the same time (for the mover is moving the moved and the moved is being moved at the same time). It is evident, then, that the movement of A, of B, of C, and of each of the moved movers will occur at the same time. Let each movement be taken, then, and let the movement of A be E, the movement of B be F, and those of C and D be G and H. For if it is always the case that each is moved by another, nonetheless we may take the movement of each as being one in number; for every movement is from something to something, and is not unlimited with respect to its extremities. By a movement that is "one in number" I mean a movement that proceeds from something numerically the same to something numerically the same in numerically the same time. For it is possible for a movement to be the same in kind, in form, or in number: in kind, if it belongs to the same category—for example, substance
242b35 or quality; in form, if it proceeds from something the same in form to something the same in form—for example, from pale to dark, or from a good to a bad that are not different in form; and in number, if it proceeds from something numerically one to something numerically one in the same time—for example, from this pale to this dark, or from this place to this place, in this time; for if in another time, the movement will no longer be one in number, but in form. But these issues were spoken about previously.[302]

And let the time in which A has been moved with its own movement also be taken, and let it be J. Since the movement of A is limited, the time will also be limited.[303] Since, then, the movers and the moved are unlimited, the movement EFGH composed of all of them will be unlimited. For it is possible for the movements of A, B, and the others to be equal, or the movements of the others may be greater, so that, whether they are equal or greater, in both cases the whole movement is unlimited. For we are assuming what is possible. And since the movement of A and that of each of the others occur at the same time, the whole movement will occur at the same time as that of A. But the movement of A is in a limited time. So there would be an unlimited movement in a limited time, which is impossible.[304]

It might thus seem, then, that what we initially set out to prove has been proved, but it has not been demonstrated, because nothing impossible has been proved; for in a limited time there can be unlimited movement, although not of one thing but of many. And this is precisely what happens in the case of these things [A, B, C, D, and so on]; for each of these is being moved with its own movement, and for many things to be moving at the same time is not impossible. But if what in a primary way causes movement with respect to place and with a bodily movement

302. 5.4.
303. 6.7.
304. 238a32–b22.

must either be in contact with, or be continuous with, what is moved, as we see to be so in all cases, then the things moved and the movers must be continuous with, or in contact with, each other, so that one thing is composed of all of them. And whether this thing is limited or unlimited makes no difference to the cases before us now; for in all cases the movement will be unlimited when the things are unlimited, if indeed the movements of the things admit of being either equal to or greater than each other; for we are assuming that what is possible is real. If, then, what is composed of ABCD is a thing that is either limited or unlimited and is moved with the movement EFGH in time J, and this is limited, it follows that in a limited time either what is limited or what is unlimited goes through an unlimited movement, which in both cases is impossible. So the series must come to a stop, and there must be a first mover and a first moved. For it makes no difference that the impossibility follows from a hypothesis; for the hypothesis that was taken is something possible, and when what is possible is posited, nothing impossible should come about because of it. **243^a30**

7.2
The Primary Mover Is Always Together with What Is Moved by It

The primary mover—not as the for-the-sake-of-which, but as the starting-point from which the movement proceeds—is together with what is moved by it (by "together" I mean that nothing is intermediate between them); for this is something common to every moved and mover. And since there are three sorts of movements, with respect to place, with respect to quality, and with respect to quantity, there must also be three sorts of movers: one that causes spatial movement, one that causes alteration, and one that causes increase or decrease. First, then, we must speak about spatial movement; for it is the primary sort of movement.

Everything, then, that is in spatial movement is moved either by itself or by something else. In the case of things that are moved by themselves it is evident that the moved and the mover are together; for the primary mover is within these things themselves, so that there is nothing intermediate in between. As for those that are moved by something else, this must occur in four ways; for spatial movements caused by something else are of four forms: pulling, pushing, carrying, and rotating. For all movements with respect to place are led back to these; for pushing along is a sort of pushing in which what is moving something away from itself follows it and continues to push it, while pushing away is when it does not follow what it has moved. Throwing is when the mover produces a movement away from itself that is more violent than the spatial movement that is in accord with nature, and in which the thing would continue to be spatially moved for as long as the imparted movement is in control. Again, pushing apart and pushing together are sorts of pushing and pulling; for pushing apart is a sort of pushing away (for the pushing away is either from the

pusher itself or from something else), while pushing together is a sort of pulling (for in fact the pulling may be toward the puller itself as well as toward something else).

So too with their forms, such as packing and combing; for the former is a sort of pushing together, the latter a sort of pushing apart.[305] And the same is true of the other sorts of aggregation and disaggregation (for they will all be found to be sorts of pushing apart or pushing together), except for the ones that are involved in coming to be and passing away. (At the same time it is evident that[306] aggregation and disaggregation do not constitute another kind of movement; for they are all divided into the ones mentioned.[307]) Further, inhaling is a sort of pulling, exhaling a sort of pushing. And the same is true of spitting and of all other movements that occur through the body, whether excretive or assimilative; for the latter are pullings, the former pushings away.

But the other sorts of movement with respect to place must also be led back [to the four forms]; for they all fall into these four. And again, of these four, carrying and rotating may be led back to pulling and pushing. For carrying is in accord with one of the other three modes (for what is carried is in movement coincidentally, because it is in or on something that is in movement, and what carries it carries it by being pulled, pushed, **244a1** or rotated, so that carrying is common to all three). And rotating is a compound of pulling and pushing; for what is rotating a thing is pulling one part of it and pushing another; for it leads one part away from itself and another part toward itself. So, if what is pushing and what is pulling are together with what is being pushed and what is being pulled, it will be evident that in movement with respect to place there is nothing intermediate between moved and mover.

But then that this is so is clear even from the definitions; for pushing is a movement away from the pusher itself, or from something else, to something else, while pulling is movement from something else to the puller itself, or to something else, when the movement of what is pulling[308] is faster than the one that would separate the continuous things from each other; for it is this way that one is pulled along with the other. (But perhaps it might seem that there is also another way of pulling; for it is not in this way that wood pulls fire.[309] But it makes no difference whether what pulls is in movement or remains at rest when it is pulling; for in the latter case it pulls to where it is, in the former to where it was.) It is impossible for a mover to move anything either from itself to something else or from something else to the mover itself without making contact with it. So it is evident that in movement with respect **244b1** to place there is nothing intermediate between the mover and the moved.

308. Retaining τοῦ ἕλκοντος.

309. The natural movement of fire is upward; burning wood, though stationary, seems to pull the fire toward itself.

But then neither is there anything between what is altered and what alters it. This is clear from induction; for in every case we find that the last thing that alters something is together with the first one that is altered {for our assumption is that what is being altered is altered by being affected with respect to its so-called affective qualities.}[310] For every body differs from another body in possessing a greater or lesser number of perceptible characteristics or the same ones to a greater or lesser degree. But then the alteration of what is altered is also due to the perceptible characteristics that were mentioned. For they are affections of the relevant underlying quality; for we say that a thing is altered by becoming hot, sweet, dense, dry, or pale, saying this alike of the inanimate as well as of the animate, and again, in the case of animate things, alike of the parts that are not capable of perception and of the perceptual modalities themselves. For the perceptual modalities themselves are also altered in a way; for active perception is a movement through the body, when the perceptual modality is affected in a certain way. Whatever way the inanimate can be altered, then, the animate can also be altered, while not every way that the animate can be altered is a way the inanimate can (for it cannot be altered with respect to the perceptual modalities). Also the inanimate is not aware of being affected, while the animate is aware. But nothing prevents the animate too from being unaware when the alteration is not with regard to the perceptual modalities. If indeed, then, the alteration of what is altered is due to perceptible things, in every case of this sort of alteration, at any rate, it is evident that the last thing that alters something and the first thing that is altered are together; for the air is continuous with what causes the alteration, and the body that is altered is continuous with the air. Again, the color is continuous with the light, and the light with the sight. And it is the same way with hearing and smelling; for the first mover relative to what is moved is the air. It is the same way in the case of tasting; for the flavor is together with the capacity of taste. And it is likewise with things that are inanimate and incapable of perception. So there can be nothing intermediate between what is altered and what alters it.

Nor, again, can there be anything intermediate between what is increased and what increases it; for the primary thing that causes the increase does so by becoming attached to what is increased in such a way that the whole becomes one. And again, what decreases something decreases it when some part becomes detached from what is decreased. It is necessary, then, for what increases something or what decreases something to be continuous with what is increased or decreased, and between continuous things there is nothing intermediate.

It is evident, then, between the moved and the mover that is primary, or last in relation to the moved, there is nothing intermediate.

7.3
Everything That Is Altered Is Altered Due to Perceptibles

That everything that is altered is altered due to perceptibles, and that there is alteration only of those things that are said to be intrinsically affected by these, is a fact that may be theoretically grasped from the following considerations. For of the others it would be most natural to suppose that there is alteration in figures and shapes, and in states, that is, in acquiring or losing them. But in neither of these two is there alteration.

For when the thing that is being configured or arranged has been completed, we do not say that it is what it is composed of—for example, we do not say that the statue is bronze, or the candle wax, or the bed wood, but using a paronym, that they are brazen, waxen, or wooden. But when a thing has been affected or altered, we still refer to it by what it is composed of; for we say that the bronze or the wax is hot or hard, and not only in this way, but we also say that the wet or the hot is bronze, referring homonymously to the matter by using [the name of] the affection. So then, **246a1** if as regards figure and shape what comes to be and has the shape in it is not said to be what it is composed of, but as regards affections and alterations it is said to be this, it is evident that the comings to be cannot be alterations.

Further, it would seem to be absurd even to speak in this way, of a human being or a house or anything whatever that has come to be as having been altered. But though each such coming to be must, perhaps, involve something's being altered, for example, the matter's being condensed or rarified or heated or cooled, nonetheless it is not the things that are coming to be, at any rate, that are altered, and their coming to be is not an alteration either.

But then the states, whether of the body or of the soul, are not alterations either. For some states are virtues and others vices, and neither virtue nor vice is an alteration. Instead, virtue is a sort of completion (for when each thing acquires its own virtue, at that point it is said to be complete—for then it is most of all in accord with its[311] nature, just as a circle is complete when it has most of all become a circle and when it is best), while vice is the passing away and departure of this completion. Just as, then, we do not speak of the completion of a house as an alteration (for it is absurd if the coping-stone or roof-tile is an alteration, or if in receiving its coping-stone or roof-tile the house is being altered but not completed), it is the same way in the case of virtues **246b1** and vices and of what possesses or acquires them; for virtues are completions and vices departures, so that they are not alterations.

Further, we say that all virtues are in [the category of] being related in a way to something. For those of the body, such as health and good condition, lie in a blending and proportion of hot and cold things, either of one in relation to another within the body or in relation to what encompasses it; and likewise in the case of beauty,

311. Retaining τὸ.

strength, and all the other virtues and vices. For each is in[312] [the category of] being related in a way to something and puts its possessor in a good or bad condition with regard to its proper affections—the proper ones being those due to which it naturally comes to be or passes away. Since, then, relatives are neither themselves alterations nor is there alteration, coming to be, or, in general, any change whatever of them, it is evident that neither states nor the losing or acquiring of them are alterations. But perhaps when these come to be or pass away some other things must be altered, as in the case of both the form and the shape—for example, hot, cold, dry, and wet things, or whatever it may be that these states first reside in. For each virtue or vice is said to be concerned with those things by which its possessor is naturally altered; for a virtue makes its possessor be either unaffectable or capable of being affected in such-and-such a way, while vice makes it be capable of being affected or unaffectable in the contrary way.

It is likewise too in the case of states of the soul; for all these also belong in [the category of] being related in a way to something, the virtues being completions, the vices departures. Further, virtue puts its possessor in a good condition with regard to its proper affections, while vice puts it in a bad one. So these will not be alterations either, and neither, then, will the losing or acquiring of them be. But for them to come to be, the perceptual part [of the soul] is necessarily altered. And it is altered by perceptibles; for every virtue of character is concerned with bodily pleasures and pains, and these lie in doing actions, in remembering, or in expectation. Those that lie in action are in accord with perception, so that it is due to something perceptible that they are moved, while those that lie in memory or in expectation are due to this; for people are pleased either by remembering what has affected them or by expecting what is going to affect them. So every such pleasure must come to be due to perceptibles. And since when pleasure and pain come to be, virtue and vice come to be as well (for they are concerned with these), and pleasures and pains are alterations of the perceptual part, it is evident that to lose or acquire these states, something must also be altered. So, though their coming to be involves alteration, they themselves are not alterations.

But then the states of the understanding part are not alterations either, nor is there any coming to be of them. For very much more [than in the case of the virtues of character] we speak of what has scientific knowledge as belonging in [the category of] being related in a way to something. Further, it is also evident that there is no coming to be of these; for what has scientific knowledge potentially comes to have scientific knowledge [actively] not at all by being itself moved but by the presence of something else. For when the particular comes to be present, the universal is in a way scientifically known by means of the particular.[313] Again, there is no coming to be of the use and activity of the state, unless one thinks that there is also a coming to be of

312. Reading ἐν.
313. *Met.* 1087ᵃ15–21.

seeing and touching; for its using and being in activity are similar to these. And the initial acquisition of scientific knowledge is not a coming to be or an alteration; for we are said to scientifically know and to be practically wise as a result of our thought's having come to rest and to a stop,[314] and there is no coming to be of being at rest, or indeed of any change at all, as was also stated previously.[315]

Further, just as when someone changes from drunkenness, sleep, or disease to the contrary states we do not say that he has come to have scientific knowledge again, and yet he was incapable of using his knowledge [while drunk, asleep, or diseased], so likewise when he initially acquires the state we must not say either [that he is coming to have scientific knowledge]; for it is due to the soul's settling down from its natural restlessness that something comes to possess wisdom or scientific knowledge. That is also why children, unlike their elders, are incapable of either learning or discerning by means of the perceptual modalities; for the disturbance and movement [in their souls] is great, and it settles down and comes to rest with regard to some things due to nature itself, and with regard to others due to other causes, but in both cases accompanied by the alteration of certain things in the body, just as in the case of the use and activity [of the understanding part] when someone becomes sober or wakes up.

It is evident, then, from what has been said, that being altered and alteration occur in perceptible qualities and in the perceptible part of the soul, and in nothing else except coincidentally.

7.4
A Puzzle Concerning the Commensurability of Movements

One might raise a puzzle as to whether every movement is commensurable with every other or not. If, then, they are all commensurable, and sameness of speed is equal movement in equal time, then a circumferential movement may be equal to a movement in a straight line, or, then, greater or less than it. Further, an alteration may be equal to a spatial movement, when in an equal time one thing has altered while another has spatially moved. An affection, therefore, may be equal to a length. But this is impossible. Or is it rather, therefore, that when in an equal time they move equally, at that time there is equal speed, but an affection is not equal to a length, so that an alteration is not equal to or less than a spatial movement, so that not all movements are commensurable?

In the case of the circle and the straight line, though, how will it be? For it is absurd if the movement of one thing in a circle is not similar to that of another in a straight line, but instead is immediately faster or slower, just as if one is downhill and the other uphill. Nor does it make any difference to the argument if one says that

314. *DA* 407a32–33, *Met.* 994b24, 1067b8–11.
315. 225b15–16.

the movement must be immediately faster or slower; for then the circumference will be greater or less than the straight line, so that they can be equal too. For if in time A [the faster X] has traversed B, and the other [the slower Y] has traversed C, then B would be greater than C; for this is what "faster" was said to mean.[316] Then too if in less time a thing traverses an equal distance, it is faster. So there will be a part of time A in which [X] traverses a part of the circle equal to [the straight line] C, while [Y] traverses C[317] in the whole time A. But then if these are commensurable, what has just been said follows, a straight line will be equal to a circle. But these are not commensurable, nor, therefore, are the movements.

But [it might be responded] it is the things that are not synonymous that are all incommensurable. For example, why is it that a pencil, a wine, and the highest note in a scale are incommensurable with respect to sharpness? Because homonymous things are not commensurable. The highest note is commensurable with the next note, because "sharp" as applied to both signifies the same thing. Is it, therefore, that fast as applied to both [X and Y] does not signify the same thing, and does so far less in the case of an alteration and a spatial movement?

Or, in the first place, is this not true: that if things are not homonymous, they are commensurable? For "much" signifies the same in the case of water as in that of air, and these are not commensurable [in this respect]. Or if not this, "double," at any rate, signifies the same (for it signifies the ratio of two to one), and these are not commensurable in this respect either. Or even in the case of these does the same argument apply? For even "much" is homonymous. Yet of some terms even the accounts are homonymous—for example, if someone were to say that "much" means such-and-such an amount plus more and that such and such an amount signifies distinct things in distinct cases. Also, "equal" is homonymous, and, if that was so, "one" would also be immediately homonymous. And if this was so, "two" would be homonymous as well, since why would some of these be commensurable and others not, if indeed they had a single nature?

Or is it because the primary recipient is distinct? A horse, then, and a dog are commensurable as to which is whiter (for what the whiteness is primarily in is the same, the surface), and similarly with respect to magnitude. But water and sound are not commensurable [with respect to whiteness and magnitude]; for what it is [primarily] in is distinct. Or is it clear that in this way all the cases will be made into one, by saying that each exists in a distinct [primary recipient], that is, the equal will be the same in each case, as will the sweet and the white, but distinct in a distinct recipient? Further, it is not any random thing that is receptive of a random affection, instead one thing is primarily receptive of one affection.

But must it therefore be the case that commensurable things are not only not homonymous but that no differences belong either to themselves or to what they are

317. Reading τὴν Γ.

in? I mean, for example, in the way that color exhibits differences; for this is surely why things are not comparable with respect to it (for example, as to which of the two is more colored, not with respect to a particular color, but insofar as it is a color), but are comparable with respect to whiteness.

Similarly, as regards movement, things have the same speed which[318] in an equal time move such-and-such an equal amount. If, then, in this [time] one [half] of a thing's length is altered while the other half is spatially moved, is the alteration equal to—that is, does it have the same speed as—the spatial movement? But that would be absurd. And the cause of this is that movement has forms. So [must we correct our statement and say that] if things in equal time spatially move an equal length, they are of equal speed? But then a straight line and a circumference will be equal. What, then, will the cause of this be? Is it that spatial movement is a kind or that line is a kind (for the time is the same in form)? Or rather are the two [the movement and the line] together divided in form?[319] For spatial movement has [different] forms if that over which the movement occurs has [different] forms. (And sometimes it has different ones if that by which it occurs has different ones—if by feet, it is walking, if by wings, flying. Or is that not so, but is it rather by its shapes[320] that spatial movement is distinguished?) So [must we correct our statement again and say that] things are of equal speed if in an equal time they traverse the same magnitude—where being the same consists in being undifferentiated in form and [thus] in the movement [over it] being undifferentiated?

So we must investigate what the differences in movement are. And the foregoing argument indicates that the kind is not something that is one, but that beyond this case there are many others that are overlooked, and that among cases of homonymy some are far removed from each other, some have some similarity to each other, and some are close either in kind or by analogy, which is why they do not seem to be cases of homonymy, though they are. When, then, is the form distinct? Is it when the same thing is in distinct subjects, or when distinct ones are in distinct ones? And what will the defining mark be? Or by what are we to discern that the white and the sweet are the same or distinct? Is it because they appear distinct in distinct subjects, or is it because there is no sameness at all?

Concerning alteration, then, how will one alteration have a speed equal to that of another? If to become healthy is to be altered, one person may be cured quickly, another slowly, and some at the same time, so that in the latter case alterations will be of equal
249b1 speed; for each was altered in an equal time. But what altered? For we cannot speak of equal here, but rather what in [the category of] quantity is equality, is here similarity. However, let things be of equal speed if in an equal time their change is the same. Is it, then, what the affection is in or the affection itself that must be commensurable? Here in our example, indeed, it is because health is the same that we may ascertain that

318. Reading τὸ.

319. Reading χρόνος ὁ αὐτὸς τῷ εἴδει ἢ ἅμα κἀκεῖνα.

320. I.e., by the different shapes of the path, whether straight, circular, or otherwise, over which it occurs.

one alteration is neither more nor less than the other but that both are similar. But if the affections are distinct, as when a thing alters by becoming pale and by becoming healthy, in these cases there is no sameness, equality, or similarity, insofar as these affections at once make the alterations differ in form, and so there is not just one form, any more than there is in the case of spatial movements. So we must ascertain how many forms there are of alterations and how many of spatial movements.

If, then, the things that are in movement—that is, the ones to which the movements belong intrinsically and not coincidentally—differ in form, then their movements will also differ in form. On the other hand, if the things differ in kind, their movements will differ in kind, and if in number, in number. But then, should we look to the affection, as to whether it is the same or similar, to find out if the alterations are of equal speed, or to the things that are being altered, as to whether, for example, so-and-so much of one has become pale and so-and-so much of the other? Or should we look to both, and regard the alterations as the same or not the same according as the affections are the same or not the same, and equal or unequal according as the things altered are equal or unequal?

And in the case of coming to be and passing away the investigation is the same: how is one coming to be equal in speed to another? They are of equal speed if in equal time two things come to be that are the same, that is, indivisible [in form]—for example, two human beings but not two animals. And one is faster than the other if in an equal time the things that come to be are distinct (for here we do not have two things between which distinctness is like dissimilarity), or, if substance is number, then within the same form one number may be greater than another. But there is no name common to these, nor is there a name for each of them, as "more" applies to a higher or superior degree of an affection and "greater" to that of a quantity.

7.5
Proportionality of Movements

A mover always moves something, in something, and as far as something (I mean by "in something" time, and by "as far as something" that the distance traversed is a certain quantity); for always when a thing is causing movement it at the same time has caused movement, so that there will be a certain quantity [of distance] that has been traversed and a certain quantity [of time] in which it has been traversed. If, then, A is the mover, B the moved, C the distance traversed, and D the time in which it is traversed, then in the same time a capacity equal to that of A will move half of B **250^{a}1** twice C, and it will move half of B the whole of C in half of D; for in this way there will be proportionality. And if the same capacity moves the same thing such-and-such a distance in a given time, and half of the distance in half of the time, then half its strength will move half the thing an equal distance in an equal time. For example, let E equal half the capacity of A and F equal half of B. Then the strength is similarly and

proportionally related to the weight in each case, so that there will be a movement of an equal distance in an equal time.

Also, if E moves F distance C in time D, it does not necessarily follow that in the same time E can move twice F half of C. If, then, A moves B distance C in time D, it is not necessary that in the time D, or in some part of it, the half of A, which is E, will move B a part of C whose ratio to the whole of C is proportional to that between A and E. For, in general, it may happen that E will not move B at all; for if the whole strength moved it so-and-so much, it does not follow that half that strength will move it any quantity in any time whatever; for otherwise one man might move a ship, if indeed the strength of the ship-haulers and the distance they all move it are divisible by their number.

This is why Zeno's argument is not true when he says that any part whatever of the millet makes a sound. For there is nothing to prevent any part from failing, in any time whatever, to move the air that the whole medimnus[321] moves when it falls. In fact, it does not even move such a part of the whole as it would move if it were by itself. For none exists except potentially in the whole.

On the other hand, if there are two movers and each of the two moves a distinct thing so-and-so much in such-and-such time, then the capacities in composition will also move the weights in composition an equal distance in an equal time; for there is proportionality.

Is it also this way, then, in the case of alteration and in the case of increase? For there is something that causes the increase, something that is increased, in so much time, and a quantity that the one causes the other to increase by and that the other increases by. Similarly, there is what alters something and what is altered, a certain quantity of alteration with respect to the more and the less, and in a quantity of time. And in twice as much time there is twice as much alteration, and twice as much in twice as much. And half in half the time, or in half the time half, or in equal time twice it.

On the other hand, if what alters something or causes it to increase does so-and-so much of it in such-and-such time, it does not necessarily follow that the half will be done in half the time, or that in half the time the half will be done. Instead, it may happen that it does not alter anything or increase anything at all, as in the case of weight.

BOOK 8

8.1
The Eternality of Movement

Did movement come to be at some time, though it did not exist before, and does it pass away again in such a way that nothing is in movement? Or is it that it neither

321. A measure of weight. Approximately 60 lbs.

came to be nor passes away, but always existed and always will exist and, being deathless and unceasing, is present in beings like a sort of life for all things composed by nature?

That there is such a thing as movement is asserted by all those who say anything about nature, because they describe the production of the cosmos, and their entire theoretical investigation is concerned with coming to be and passing away, which could not exist if movement did not exist. But those who say that there are unlimited cosmoses,[322] some coming to be and some passing away, are saying that there is always movement (for these comings to be and passings away necessarily involve movement), while those who say that there is one cosmos, or one[323] that did not always exist, also make assumptions about movement that are in accord with their account.

If, then, it is possible that at some time nothing is in movement, this must come about in one of two ways; for either it will be as Anaxagoras says (for he says that all things were together and at rest for an unlimited time, and then the [divine] understanding produced movement in them and disaggregated them) or as Empedocles does, with things being in turn in movement and again at rest—in movement when love makes one from many or strife makes many from one, and at rest in the intermediate times, as he says:

> Thus insofar as they have learned to grow into one from more than one,
> And in turn, with the one growing apart, to become more than one,
> They come to be and do not have a steadfast life: **251^{a}1**
> But insofar as they alternate continually without cease,
> They are always immovable in a circle.[324]

For by "but insofar as they alternate" we must take him to mean from this to that. We must investigate, then, how things stand as regards these issues; for to see the truth will advance the work not only of the theoretical investigation concerned with nature, but also of the methodical inquiry concerned with the primary starting-point.[325]

Let us start first from what we previously determined in the *Physics*.[326] We say,[327] then, that movement is the activation of the movable, insofar as it is movable. For each sort of movement, therefore, there must exist things that are capable of moving. In fact, even apart from the definition of movement, everyone would agree that for each sort of movement it must be what is capable of the movement that is in movement—for example, it is what is alterable that is altered and what is changeable

322. E.g., Leucippus, Democritus, and, though less certainly, Anaximander.
323. Rejecting the addition of ἢ ἀεὶ.
324. B17.9–13 DK.
325. I.e., that conducted in the *Metaphysics*.
326. Aristotle sometimes contrasts Book 8 with the *Physics*, as he here contrasts it with 3.1, and with other books at 253^{b}8 (Book 2), 257^{b}1 (Book 6), 267^{b}21–22 (Book 3 again). But these terms have no fixed reference for him. Thus *Met*. 1073^{a}32 uses "the *Physics*" to refer to 8.8–9.
327. 201^{a}10–11.

with respect to place that is in spatial movement. So there must be a burnable before there is a being burnt, and a capable of burning something before there is an act of burning. These things too, then, must come to be at some time, having not existed previously, or they must always exist.

Therefore, if each of the movable things came to be, then, before the movement in question, there must have been another change and movement in which the thing capable of being moved or of moving something came to be. But if such things always preexisted without there being any movement, it is manifestly absurd when we first stop to think about it, and must become still more so as we go on doing so. For if some things are movable while others are capable of moving things, then if there is a time when there is a first mover and a first moved, and another time when there is no such thing, but rather things are at rest, these ones must have changed previously; for there was some cause of their being at rest; for rest is a privation of movement. So prior to the first change there will be a previous change.

For some things move things in only one way, while others do so with contrary movements—for example, fire heats but does not cool, while the science of contraries seems to be one science. There appears to be something similar occurring even in the former case (for cold heats in a way by turning aside or retiring, just as the person with scientific knowledge errs voluntarily when he uses his scientific knowledge in the reverse way), but things, at any rate, that are capable of affecting or being affected, or of moving something or being moved, are not capable of it under all conditions, but only if they are in a certain condition and are near each other. So when one thing has approached another, it moves it, and the other is moved, that is, when one was such that it was capable of moving the other and the other of being moved. If, therefore, the movement was not always going on, it is clear that they were not in a condition such that the one was capable of being moved and the other capable of moving it, but rather one of them had to change; for in things that are related it is necessary for this to happen—for example, if one thing was not double another but is double it now, one of the two, if not both, must have changed. Therefore, there will be a change previous to the first change.

{In addition to these considerations, how will there be a before and after if time does not exist? Or how will there be time if movement does not exist? If time is really a number of movement or a sort of movement, if indeed there is always time, movement too must be eternal. But then in the case of time, at least, all—with a single exception—are manifestly of one mind; for they say that it does not come to be. In fact it is because of this that Democritus in particular proves how it is impossible for everything to have come to be; for time does not come to be. Plato alone makes it come to be; for he says[328] it exists together with the heaven, and that the heaven came to be. If, then, it is impossible for time to exist or to be understood without the now, and if the now is a sort of intermediate, and involves a starting-point and an

328. *Timaeus* 38b.

end-point at the same time, a starting-point of the future time and an end-point of the past time, it follows that time must always exist. For the extremity of the time taken as last will lie in a certain one of the nows (for there is nothing to take in the time besides the now), so that since the now is both a starting-point and an end-point, there must always be time on both sides of it. But if time does exist, it is evident that movement must exist as well, if indeed time is a sort of affection of movement.}[329]

The same argument also applies to movement's not being capable of passing away; for just as the coming to be of movement implied the existence of a change previous to the first, in the same way here it implies the existence of one later than the last; for a thing does not cease being in movement and being movable at the same time, for example, being burned and being burnable (for it is possible for something to be burnable without being burned), and neither do being capable of moving something and moving it. And what is capable of causing something to pass away will have to pass away after it has caused it to pass away, and what is capable of causing this to pass away will in turn have to pass away later; for passing away is also a sort of change. If, then, these things are impossible, it is clear that there is eternal movement, not something that existed at one time, but not at another. In fact, to say such things seems more a matter of fabricating stories.

And the same is true for saying that things are naturally this way and that one must acknowledge it as a starting-point, which is precisely what Empedocles would seem to be saying, that for love and strife alternately to rule and cause movement holds of things by necessity, and for there to be rest in the intermediate time. And maybe those who posit a single starting-point of movement, such as Anaxagoras, would also speak in this way. But surely there is nothing, at any rate, disorderly in things that happen by nature or in accord with nature; for nature is a cause of order in everything. Between one unlimited thing and another unlimited thing, however, there is no ratio, while all order is ratio. But for things to be at rest for an unlimited time, then in movement at some time, and no difference at all to cause this happening now rather than earlier, and with no order of any sort involved either, is no longer a work of nature. For what holds by nature is either simple, and not sometimes one way and sometimes another (for example, fire spatially moves upward by nature, and not sometimes up and sometimes not) or, if not simple, it involves some ratio.

That is why it is better to say with Empedocles, or anyone else who may have spoken as he does, that the universe is alternately at rest and in movement again; for such a state of affairs already involves some sort of order. But even someone who says this must not only state it but also say what the cause of it is—and he must neither merely posit something or assume an un-argued axiom, but must produce either an induction or a demonstration; for the things assumed [by Empedocles] are not

329. Since this section interrupts the main argument of the chapter, it may be either a digression or a later insertion.

themselves causes of this alternation, nor was it the being for love or for strife to cause it, but for the one to aggregate and for the other to disaggregate. And if he is going to go on to determine the details of their alternation, he must say under what conditions it happens, just as he says that there is something—love—that causes human beings to aggregate, and that enemies flee each other; for he assumes that this also holds in the whole cosmos, because it is apparently so in some cases. And that love and strife rule for equal periods of time also requires some argument.

In general, to think that this is an adequate starting-point, that something always is or comes to be in this way, is an incorrect assumption to make. Thus Democritus refers back causes concerned with nature to the fact that this is how things also happened previously. Of what always happens, however, he does not think it fitting to seek a starting-point, which in some cases is a correct thing to say, but that it holds in all cases is not correct. For in fact a triangle has its angles always equal to two right angles as well, but nonetheless there is some other cause of the eternality of this, although of starting-points that are eternal there is no other cause.

As regards the view, then, that there never was a time when movement did not exist, nor will be one when it will not exist, let this much be said.

8.2
Puzzles about the Eternality of Movement

The claims that go contrary to these are not difficult to refute. For it is when people investigate on the basis of considerations like the following that it might most of all seem to be possible for movement to exist though at one time it had not existed at all:

First, no change is eternal; for every change is naturally from something to something, so that every change has as its limits the contraries between which it takes place, and no movement goes on without limit.

Further, we see that it is possible for something to be moved that is neither in movement nor has any movement whatever within itself—for example, in the case of inanimate things that are not in movement, either in any part whatever or as a whole, but are at rest, we see them being moved at some time. But they must be either always in movement or never, if indeed movement does not come to be when it has not existed previously.

This is by far most evident in the case of animate things; for sometimes, though there is no movement whatever in us and we keep still, nonetheless at some moment we are in movement, and a starting-point of movement comes to exist in us from ourselves, even if nothing external moves us. We do not see anything like this in the case of inanimate things, but are always moved by some other external thing. But the animal, we say moves itself. So, if indeed an animal is sometimes altogether at rest, movement might come to exist in an unmoving thing from itself and not from outside. But if this can happen in an animal, what prevents the same thing from

happening throughout the universe? For if it happens in the microcosm, it can also happen in the macrocosm. And if in the cosmos, then also in the unlimited, if indeed it is possible for the unlimited to be in movement or at rest as a whole.

Among these considerations, then, the first mentioned—that movement to opposites is not always the same and one in number—is correct. For this is perhaps necessary, if indeed it is possible for the movement of what is one and the same to be not always one and the same. I mean, for example, there is a question as to whether the note from a single string is also one and the same, or a distinct one each time, although the string is in the same condition and moves in the same way. But whatever the case may be, nothing prevents some movement from being the same and eternal by being continuous. This will become clearer from what we say later.[330]

253^{a}1 As for what was not in movement being moved, it involves nothing absurd if an external mover of it is sometimes present, sometimes not. We must, however, inquire about how this can happen, I mean, that the same thing is at one time moved by the same mover capable of moving it and sometimes not; for the one who says this does nothing other than raise the puzzle as to why it is that some things are not always at rest and others always in movement.

The third consideration might seem to involve the greatest puzzle, as to how movement can come to be in things it was not present in before, which is what happens in the case of animate things; for one previously at rest walks later, although nothing external moved it, as it seems. But this is false. For we always see that some innate part in the animal is in movement. And of the movement of it the animal itself is not the cause, but perhaps what encompasses it is. It itself, we say, moves itself not in the case of every sort of movement, but in the one with respect to place. Nothing prevents, then, many movements from coming to be in the body due to what encompasses it (or rather it is presumably necessary for this to be so), and of these some move thought or desire, and that in turn moves the whole animal. This happens, for example, in cases of sleep. For although no internal perceptual movement takes place at all, yet some sort of internal movement does, and the animal wakes up again. But in fact about these issues too things will be evident from what follows.[331]

8.3
Immobility and Movement

The starting-point of our investigation will also be[332] precisely the one having to do with the puzzle that has just been mentioned: why some beings are sometimes in movement and in turn sometimes at rest. But necessarily either all things are always at rest, or all things are always in movement, or some things are in movement and

330. 8.8.
331. 259^{b}1–16.
332. Reading ἔσται ἥπερ.

some at rest, and in this last case again either the things in movement are always in movement and the things at rest always at rest, or all things are alike naturally in movement or at rest, or the remaining and third alternative. For it is possible for some beings to be always unmoved, others always in movement, while some have a share in both conditions. And this is precisely the one that we must assert; for this holds the resolution of all the puzzles we raised, and is the end for us of this present study.

To say that all things are at rest and to seek an account of it, disregarding perception, is a sort of lack of eagerness in thinking, a disputing of the whole rather than some part of it, and is directed not only against the natural scientist, but against (one might almost say) all the sciences and all beliefs, because all of these make use of movement. Further, just as in accounts concerned with mathematics objections to starting-points are not directed against the mathematician, and likewise in all the other cases, so the position stated just now is not directed against the natural scientist; for it is a hypothesis for him that nature is a starting-point of movement.

To say that all things are in movement is also pretty much false, though less contrary to our methodical inquiry;[333] for in the *Physics* nature was posited as a starting-point of rest as well as of movement, and likewise[334] movement as something caused by nature. In fact, some thinkers maintain not that some of the beings are in movement and some not, but that all of them always are, though our perception fails to notice this. Although they do not define what sort of movement they mean, or whether they mean all sorts, it is not difficult to reply to them. For increase and decrease cannot go on continuously, but there is also what is intermediate. The argument is like the one that deals with dripping water wearing away stones and plants splitting them by growing up through them; for if so-and-so much was driven out or taken away by the dripping water, it does not follow that half that much was previously driven out or taken away in half the time. But just as in the case of hauling a ship, so-and-so many drops move so-and-so much, but a part of them does not move that much in any period of time. What is taken away, it is true, is divisible into many parts, but none of those was moved separately, but all were moved together. It is evident, then, that from the fact that decrease is divisible without limit it does not necessarily follow that some part is always being taken away, but rather that the whole is at some time taken away.

It is likewise in the case of any sort of alteration whatever; for if what is altered is divisible without limit into parts, it does not follow because of this that the alteration itself is as well; on the contrary, it often happens all at once, as in the case of solidification. Further, whenever someone has fallen ill, there must be a time during which he will become healthy [if he does]—he cannot change [instantly] at the end of time. And the change must be to health and to nothing else. So to say that alteration is continuous is to dispute what is far too evident to dispute. For alteration is to what is contrary, while the stone becomes neither harder nor softer. And as regards spatial

333. Than to say that all are at rest.
334. Reading ὁμοίως.

movement, it would be a wonder if it escaped our notice whether it was in spatial movement downward or resting on the earth. Further, earth and each of the other elements necessarily remain in their proper places and are removed from them [only] by force. If indeed, then, some of them are in their proper places, it is necessary that not all things be in movement with respect to place. **254^{a}1**

From these and other such arguments one may be persuaded, then, that it is impossible either for all things to be always in movement or for all to be always at rest.

But then it is not possible either for some things to be always at rest and some things to be always in movement, but for nothing to be at rest at one time and in movement at another time. And we must say that it is impossible in these cases too on just the grounds that it was in the previous cases we described (for we see the sorts of changes we mentioned occurring in the same things), and, in addition, that the person who disputes this is in conflict with the evident facts; for there can be no such thing as increase, nor will movement by force occur, if nothing that is previously at rest will be moved contrary to nature. This account, then, does away with coming to be and passing away. But movement seems to pretty much everyone to be a sort of coming to be and passing away; for what something changes to, it comes to be this, or in this, and what it changes from, it ceases to be this, or in this. So it is clear that there are things that are sometimes in movement and sometimes at rest.

The claim that all things are sometimes at rest and sometimes in movement must at this point be brought together with the arguments just given. And, drawing on the present distinctions, we must again posit a starting-point, the very same one from which we started previously. For surely either all things are at rest or all are in movement, or some are at rest and some in movement. And if some are at rest and others are in movement, then, of necessity, either all of them are sometimes at rest and sometimes in movement, or some are always at rest and others always in movement, or some are always at rest, some always in movement, while some are sometimes at rest and sometimes in movement. It was stated previously[335] that it is not possible for all things to be at rest, but we must state it again now. For even if things are truly in this state, as certain people assert,[336] and being is unlimited and immovable, at least, it does not at all appear to be that way according to perception, but instead many beings appear to be in movement. If indeed, then, there is false belief, or belief at all, there is movement too; even if this belief is an imagination, or if things seem to be sometimes one way and sometimes another way. For imagination and belief seem to be sorts of movements. But to investigate this question at all, and to seek an argument when we are too well off to need an argument, is to be a bad judge of what is better

335. 253^{a}32–^{b}6.
336. E.g., Melissus (185^{a}32, 186^{a}16).

and what is worse,[337] and what is persuasive and what is not persuasive, and what is a starting-point and what is not a starting-point.

It is likewise impossible too for all things to be in movement or for some things to be always in movement and the others always at rest. For against all these views one mode of persuasion is enough; for we see some things that are sometimes in movement and sometimes at rest. So it is evident that for all things to be at rest or in movement continuously is just as impossible as for some to be always in movement while others are always at rest.

It remains, then, to get a theoretical grasp on whether all things are such as to be capable of being in movement and of being at rest, or whether some are like this while some are always at rest and some always in movement; for it is this latter that we must prove.

8.4
Whatever Is in Movement Is Moved by Something

Among things that cause movement or are moved, some cause movement or are moved coincidentally, some intrinsically—coincidentally, for example, by belonging to the movers or moved, or with respect to their parts, and intrinsically, not by belonging to the mover or the moved, or by a part of them causing movement or being moved.

Among the intrinsic movements, some are due to the thing itself, some due to something else, and some are by nature, others by force and contrary to nature. What is moved by itself is in effect moved by nature, as in the case of each animal (for an animal is moved by itself, and things that have the starting-point of movement within themselves we say are moved by nature; which is why the animal as a whole moves itself by nature, yet its body may be moved both by nature and contrary to nature; for it makes a difference what sort of movement it happens to be moved in and from what element it is composed). And of things that are moved by something else, some are moved by nature and some contrary to nature—contrary to nature, for example, earthen things moving upward and fire downward. Further, the parts of animals are often moved contrary to nature, that is, contrary to their [normal] positions and modes of movement. Also, that what is in movement is moved by something else is most of all evident in the case of things that are in movement contrary to nature, because it is clear that they are moved by something else. And after the contrary-to-nature cases, the next most evident of those that are in accord with nature, are the ones that move due to themselves—for example, animals; for what is unclear in this case is not whether they are moved by something, but rather how we should distinguish in them between the cause of movement and the moved; for just

337. *Met.* 1006[a]5–8.

as in ships and things not composed by nature, so too in animals the mover and the moved seem to be distinct, and in this way the entire animal moves itself.

What is most puzzling is the remaining case of those we last distinguished;[338] for of things moved by something else we posited that some are moved contrary to nature, while some are left opposed to these because they are moved by nature. It is these cases that produce the puzzle as to what they are moved by—for example, in the case **255^{a}1** of light and heavy things. For these are moved to the opposite places by force, but to their proper places—the light up, the heavy down—by nature. But what they are moved by is no longer evident, as it is when they are moved contrary to nature. For it is impossible to say that they are moved by themselves; for this is characteristic of life and is special to animate things. Also, they would have been capable of stopping themselves (I mean, for example, if a thing is cause of its own walking, it is also cause of its own not walking), so that if it is up to fire itself to spatially move upward, it is clear that it is up to it to spatially move downward as well. It is also unreasonable for things to move themselves with only one sort of movement, if at any rate they do move themselves.

Further, how is it possible for something that is continuous and naturally unified to move itself? For insofar as a thing is one and continuous not by contact [of its parts], it is unaffectable; but it is insofar as it is separated into parts that one part naturally affects and the other is naturally affected. Therefore, none of the things under discussion move themselves (for they are naturally unified), nor does anything else that is continuous, but rather the mover must be divided in each case from the moved, as we see in the case of inanimate things when an animate one moves them.

It turns out, however, that these things too are always moved by something, as would become apparent if we divided the causes. And it is in fact possible to apply to movers the division that was mentioned; for some of them are capable of moving things contrary to nature (for example, it is not by nature that a lever is capable of moving what is heavy), while other things are capable of doing so by nature (for example, the actively hot is able to move the potentially hot, and similarly in other such cases).

In the same way too what is movable by nature is what is potentially of a certain quality or quantity or in a certain place, when it has the corresponding starting-point within itself and not coincidentally (for the same thing may have a quality and a quantity, but the one might belong to the other coincidentally and not intrinsically). When fire and earth, then, are by force moved by something, they move contrary to nature, but they do so by nature when, while in potentiality, they proceed to their own activities.

But since something is said to be potentially something in many ways, this is the cause of its not being evident what such things are moved by—for example, fire up and earth down. The learner is potentially a scientific knower in another

338. 254^{b}20–22.

way than the one who already has the scientific knowledge but is not activating it. Sometimes[339] the potential becomes active, and always does so when what is capable of affecting and what is capable of being affected come together—for example, the learner from being potentially one thing becomes potentially another thing (for the one who has scientific knowledge but is not contemplating is in a way potentially a scientific knower, but not in the way he was before he learned). And whenever he is in this latter state, if nothing prevents him, he activates his scientific knowledge and contemplates; otherwise he would be in the contradictory state, that is, in one of ignorance.

The situation is similar in the case of natural things; for the cold is potentially hot, and whenever it changes, by this time it is fire, and it burns, unless something prevents or impedes it. And it is likewise with the heavy and the light; for the light comes to be from the heavy, for example, air from water (for water was first potentially air), and by the time it is light, it will at once be active, if nothing prevents it. The activity of the light is to be somewhere (up) and it is prevented whenever it is in the contrary place. And the situation is similar both in the case of quantity and in that of quality.

And yet this is what is being inquired about: why it is that the light and the heavy do move to their own place. And the cause is that it is natural for them to be somewhere, and this is the being for the light and the heavy, the one being determined by up and the other by down. Things, though, are potentially light and heavy in many ways, as was said; for when something is water, it is in a way at least potentially light, and when it is air, it is still potentially light (for something may impede it from being up). But if the impediment is removed, it becomes active and moves always upward. In a similar way a quality too changes to being active; for the possessor of scientific knowledge contemplates immediately, if nothing prevents it. And a quantity[340] is expanded [immediately], if nothing prevents it. And the one who moves the thing that remains there and prevents in a way causes movement and in a way does not—for example, the one who pulls away a supporting pillar or removes a stone from a wineskin in the water;[341] for he moves the thing coincidentally, just as the ball that bounced back was moved not by the wall but by the thrower. It is clear, therefore, that none of these things moves itself. However, each does have a starting-point of movement, not of causing movement or of affecting, but of being affected.

If, then, all things that are in movement are moved either by nature or contrary to nature and by force, and if things moved by force and contrary to nature are all moved by something, and something other than themselves, and if, in turn, things moved by nature are moved by something, both those moved by themselves and those not moved by themselves (for example, the light and the heavy—for they are moved either by what caused them to come to be and made them light or heavy, or

339. Reading ἐνίοτε.

340. I.e., one that is being compressed.

341. The wineskin is full of air, like a balloon, and is being held underwater by a stone, whose removal in a way causes it to float to the surface.

by what removed the thing that was impeding or preventing), then all things that are in movement are moved by something.

8.5
The Primary Mover Is Immovable

And this will happen in one of two ways. Either it is not through itself[342] that the mover moves the thing, but rather it is through something else that moves the mover, or it is through itself, and this latter mover will act either first after the last [movement] or through several intermediates—for example, the stick moves the stone, which is moved by the hand, which is moved by the human being, who is no longer moved by anything else.[343]

We say, then, that both things cause movement, both the last and the first mover, but more so the first; for it moves the last, but the last does not move the first, and without the first the last will not move anything, while the first will do so without the last—for example, the stick will not move anything if it is not moved by the human.

If, then, everything that is in movement must be moved by something, and either by something moved by something else or not, and if it is moved by something else, there must be some first mover that is not moved by anything else, while if the first mover is not moved by something else, there is no necessity for the other sort of mover (for it is impossible for a series of movers that are moved by something else to go on without limit; for of unlimited series there is no first member)—if, then, everything that is in movement is moved by something, and the first mover is moved, but not by anything else, it must be moved by itself.

Further, it is also possible to go through the same argument in the following way. For every mover moves something by means of something. For the mover moves either by means of itself or by means of something else—for example, a human being moves something either by means of himself or by means of a stick, and the wind knocked something down either by means of itself or by means of a stone driven by it. But it is impossible for a mover to move something without moving by means of itself that by means of which it moves the thing. But if it moves it by means of itself, there is no necessity for there to be anything else by means of which it causes movement while if there is something else by means of which it causes movement, there must be something that causes movement not by means of something [else] but by means of itself, or the series will go on without limit. If, then, a thing that is in movement causes movement, it is necessary for the series to stop and not go on without limit; for if the stick causes movement by being moved by the hand, the hand moves the stick, while if something else causes movement by means of the hand,

342. Reading δι' αὑτὸ.
343. *NE* 1139[a]31–[b]5.

then something else is the mover of the hand as well. Whenever, then, movement by means of something is at each stage caused by something else, there must be some prior thing that causes movement by means of itself. If, then, this thing is moved, but nothing else is the mover of it, it must move itself. So according to this argument too,
256b1 either what is moved is immediately moved by something that moves itself or at some time the series arrives at such a thing.

And if, in addition to the things we have just said, we investigate in the following way, these same conclusions will result. For if everything that is in movement is moved by something that is in movement, either this condition belongs to the mov-
5 ers coincidentally, so that each of them causes movement while being in movement, but not because it is itself in movement, or it does not belong coincidentally but intrinsically. In the first case, if the mover is in movement coincidentally, it is not necessary for it to be moved. But if this is so, clearly it is possible that at some time no being is in movement; for what is coincidental is not necessary but admits of
10 not being. If, then, we posit what is possible, nothing impossible will result, but presumably a falsehood may. But for there to be no movement is impossible; for it was proved previously[344] that there must always be movement.

Also, this result is reasonable. For there must be three things: the moved, the
15 mover, and that by means of which the mover moves. The moved must be in movement, but it is not necessary for it to move anything, while that by which the mover moves must both move something and be in movement; for it changes together with, at the same time as, and in the same respect as the moved. This is clear in the case of things that cause movement with respect to place; for the movers and the moveds must be making contact with each other up to a certain point. But what moves in such a way as not to be that by which it moves is immovable. And since
20 we see the last thing, what is capable of being moved but does not have a starting-point of movement, and also see what is moved by another but not by itself,[345] it is reasonable, not to say necessary, to suppose that there is also a third thing that causes movement while being immovable. That is why Anaxagoras speaks correctly
25 when he says that the [divine] understanding is unaffectable and unmixed,[346] since, at any rate, he makes it the starting-point of movement; for only in this way could it cause movement while being itself immovable, and only by being unmixed have supreme control.

But then if the mover is moved not coincidentally but necessarily, and if it were not moved, would not move anything, it is necessary for the mover, insofar as it is
30 moved, to be moved so that[347] it is in accord with the same form of movement [as the movement caused by it], or in accord with a distinct one. I mean, for example, either that what is heating something is itself being heated, what is making something

344. 7.1.
345. Reading ὑπ᾽ ἄλλου δὲ ἀλλ᾽ οὐχ ὑφ᾽ αὑτοῦ.
346. *DA* 429a18–27.
347. Reading ὥστε.

healthy is becoming healthy, and what is carrying something is being carried, or that what is making something healthy is being carried and what is carrying something is being increased in size. But it is evident that the latter is impossible; for one must speak [of the movements] by dividing as far as the indivisible [forms]—for example, one must say that if someone is teaching some topic in geometry, he is being taught **257a1**
this same topic, and that if he is throwing something, he is being thrown in the same manner of throwing. Or it may not be this way, but one kind may derive from another—for example, what is causing spatial movement is increasing in size, and what is causing this increase is being altered by something else, and what is causing 5
this alteration is being moved with another sort of movement. But this series must stop; for the sorts of movements are limited. And to say that the series bends back again, and that what is causing the alteration is spatially moving is to do the same as if one said immediately that what is causing spatial movement is spatially moving, and the one who is teaching is being taught (for it is clear that everything that is moved is also moved by the mover that is higher up in the series, and more so by the prior of 10
two movers). But this is impossible; for it follows that the one who is teaching is the one who is learning—although the one must have, and the other not have, scientific knowledge.

Further, what is still more unreasonable is that it follows that everything that is capable of causing movement is capable of being moved, if indeed everything that 15
is moved is moved by something that is moved. For it will then be capable of being moved, just as if someone said that everything that is capable of making something healthy is capable of being made healthy, and that everything capable of building is capable of being built, either immediately or through several intermediaries. I mean, for example, if everything that is capable of causing movement is capable of being moved by something else, but not with the same sort of movement with which it moves its neighbor, but with another sort (for example, what is capable of making 20
something healthy is capable of learning), and, by going up through the series, we at some time arrive at the same form of change, as we said earlier.[348] The first alternative is impossible, and the second is fabricated; for it is absurd that what is capable of altering something must be capable of being increased. It is not necessary, therefore, for what is moved always to be moved by something else that is itself moved. There- 25
fore, the series will stop. So either what is first moved will be moved by something at rest, or it will move itself.

But then if there were in fact any need to investigate whether it is what moves itself or what is moved by something else that is cause and starting-point of movement, everyone would take it to be the former; for what is itself intrinsically a cause is always prior as a cause[349] to what is itself a cause [but] in virtue of something else. So we 30

348. 257^a7–12.
349. Reading αἴτιον ἀεὶ πρότερον.

must investigate this by making a fresh start: if something moves itself, how and in what manner does it cause movement?

It is necessary for everything that is in movement to be divisible into parts that are always divisible; for it was proved previously[350] in our universal discussions about
257ᵇ1 nature that everything that is intrinsically moved is continuous. It is impossible, then, for what moves itself to move itself in its entirety; for it would be spatially moved as a whole, and it would spatially move itself with the same spatial movement, while being one and indivisible in form, and it would be altered and alter itself, so that it would be teaching and learning at the same time, and making healthy and being made
5 healthy with the same health. Further, it was determined[351] that it is the movable that is moved; but the movable is in movement potentially, not actually. But what is potentially proceeds to actuality, and movement is the incomplete actualization of what is movable. The mover, on the other hand, is already in activity—for example, what is hot heats, and, in general, what has the form generates. So, [if a thing can
10 move itself as a whole,] the same thing will be hot and not hot at the same time in the same respect, and likewise in each of the other cases in which the mover and the moved must be synonymous. Therefore, one part of what moves itself is the mover and another part is the moved.

But that it is not self-moving in such a way that each of the two parts are moved by the other is evident from the following considerations. For, first, there will be no first
15 mover at all, if each part does move the other[352] (for the prior mover is more of a cause of the movement than what comes next in the series, and more of a mover; for we saw that there are two ways to move things, by being moved by something else and by being self-moved; and what is further from the last thing that is moved is closer to the starting-point of movement than what is intermediate). Further, it is not necessary
20 for the part that is the mover to be moved except by itself. It is coincidental, therefore, if the other part moves it in return. We may take it, therefore, that it is possible for it not to move it. One part is moved, therefore, while the other is an immovable mover. Further, it is not necessary for the mover to be moved in return. On the contrary, either it must move something while being immovable or it must be moved by itself,
25 if indeed there must always be movement. Further, a thing would be moved with the movement it causes, so that what heats would be heated.

But then no primary thing that moves itself has one or more parts each of which moves itself. For if the whole is moved by itself, it will either be moved by one of its parts or the whole will be moved by the whole. If, then, it is moved by some part
30 being moved by itself, this part would be the primary self-mover (for separated it will move itself, while the whole will no longer do so). If, on the other hand, the whole is moved by the whole, it would be coincidental that the parts moved themselves. So,

350. 234ᵇ10–20.
351. 251ª9–16.
352. Reading εἴ γε ἑκάτερον κινήσει ἑκάτερον.

if it is not necessary that they do so, the case in which they are not moved by themselves may be taken. Of the whole [cause], therefore, one part will cause movement while being immovable, while the other will be moved; for only in this way will it be possible for something to be self-moved. **258a1**

Further, if indeed the whole moves itself, a part of it will cause movement and a part will be moved. AB will be moved, therefore, both by itself and by A alone. And since what causes movement may either be moved by something else or be immovable, and what is moved may either move something or move nothing, the self-mover must be composed of a part that is immovable but causes movement, and further of a part that is moved but does not necessarily move anything, but may or may not do so. For let A be the part that causes movement but is immovable, and B the part that is moved by A and moves C, which is moved by B but moves nothing; for even if C is in fact reached through several intermediates, let us suppose it is reached through only one. The whole ABC, then, moves itself. But if I take away C, AB will move itself, A causing movement and B being moved, while C will not move itself or be moved at all. But then neither will BC move itself without A; for B causes movement by being moved by something else, not by being moved by any part of itself. Therefore, AB alone moves itself. It is necessary, therefore, for what moves itself to have a part that causes movement but is immovable and a part that is moved but does not necessarily move anything, with either both parts making contact with each other, or one of the two with the other. If, then, the mover is continuous (for what is moved must be continuous), each part will make contact with the other. It is clear, then, that the whole moves itself not by a part being such as to move itself, but instead it moves itself as a whole, being moved and causing movement by a part of it being the mover and a part the moved. For it does not cause movement as a whole nor is it moved as a whole, but instead it is A that causes movement and B alone that is moved.

A puzzle arises, however, if one takes something away either from A (if the immovable mover is continuous) or from B (the part which is moved): will what remains of A cause movement or what remains of B be moved? For if so, AB would not be the primary thing that is moved by itself; for when something is taken away from AB, what remains of AB will still move itself. Or is it rather that nothing prevents either both parts or, at any rate, one part—the moved one—from being potentially divisible but actually undivided, if when divided it no longer has the same nature? In that case, nothing prevents the primary self-mover from being in what is potentially divisible. **258b1**

It is evident from these considerations, therefore, that there is a primary mover that is immovable; for [the series of] what is moved, and is moved by something else, stops either immediately at an immovable mover, or at something moved, but that moves itself and stops itself; in either case the primary mover of all moved things is immovable.

8.6
The Primary Mover Is One and Eternal

Since there must always be movement without intermission, there must be something eternal, whether one thing or more than one, that first causes movement. And what is a first mover must be immovable. Whether each of what is immovable but a mover is eternal is not relevant to the present argument, but that there must be something that is immovable and outside all change, both unconditionally and coincidentally, but which is capable of moving something else, will be clear if we investigate in the following way.

Let it be granted, then, if you wish, that in the case of certain things, it is possible for them at times to be and at times not to be, without any process of coming to be or passing away (for perhaps it is necessary, if something without parts at one time is and another time is not, that anything of that sort should, without undergoing any process of change,[353] at one time be and another time not be). And of the starting-points that are unmoving but can cause movement, let it also be possible for some of them to be at one time and not be at another. Even so, this is not possible for all of them; for it is clear that there is some cause of the self-movers being at one time and not being at another. For everything that moves itself must have magnitude, if nothing without parts is in movement, but for the mover to have it is not at all necessary, given what we have said.

That some things, then, come to be and some pass away, and that this happens continuously, of this, no immovable thing that is not eternal could be the cause, nor, again, could one that moves some things, while others move others.[354] For of the eternity and continuity neither each of them nor all can be the cause; for this state of things exists eternally and of necessity, while, though the sum of all those movers is unlimited, they do not all exist at the same time. It is clear, therefore, that even **259ᵃ1** if some of the immovable movers and many of the self-movers pass away countless times, and others succeed them, and even if one thing that is immovable moves one thing while another moves another, nonetheless there is something that encompasses them all, and this, which is beyond each of them, is the cause of some things existing and others not, and of the continuous process of change. And this causes the movement of these other movers, while they cause the movement of the other [beings].

If indeed, then, movement is eternal, the first mover will also be eternal, if there is one. But if there are several, there will be several eternal movers. But we must believe that there is one rather than many, and a limited rather than an unlimited number; for when the consequences are the same, we must always take the limited number; for in things that are by nature, what is limited and better must, if it is possible, be

353. *Sens.* 446ᵇ2–4, *Met.* 1002ᵇ6–7, 1044ᵇ21–22, 1043ᵇ14–18.
354. Reading οὐδ᾽ αὖ τῶν ἀεὶ μὲν ταδί κινούντων, τῶν δ᾽ ἕτερα.

present to a higher degree. And in fact one is enough, the first of the immovable movers, which, being eternal, will be the starting-point of movement for the others.

It is also evident from the following considerations that the first mover must be something that is one and eternal. For it has been proved that there must always be movement. But if it always is, it must be continuous; for in fact what always exists is continuous, while what is successive is not continuous. But then if it is continuous, it is one. And it is one if the mover is one and what it is moved also one; for if the movement were to be caused by one thing, then by another, the whole movement would not be continuous but successive.

On the basis of these considerations, then, one may be persuaded that there is some first immovable mover, and also by looking again at the starting-points of movers.[355] It is evident, then, that there are some beings that are at times in movement and at times at rest. And because of this it has become clear that it is not the case either that all things are in movement or that all are at rest or that some things are always at rest and the others always in movement; for things that play a double game and have the capacity to be in movement and to be at rest prove the truth about these alternatives. And since the existence of such things is clear to all, we wished to prove the nature of the other two sorts of things, and prove that there are some things that are always immovable and some things that are always in movement. Proceeding toward this end, and having established[356] that everything that is moved is moved by something, and that this thing is either immovable or moved, and that, if it is moved, it is moved either by itself or by another at each stage, we advanced[357] to the point of grasping that the starting-point of the movement of things that are in movement is, among moving things, the self-mover, but among all things, the immovable mover. But we see that beings that move themselves are manifestly of this sort—for example, **259b1** the animate ones and the kind of animals. And these in fact yielded the belief that perhaps it may be possible for movement to come about without having existed previously at all, because we see this happening in these things (for at one time they are unmoving and then they are in movement once again, so it seems). But[358] we must grasp the fact that animals move themselves with only one sort of movement, and that even regarding it they do not do so in the strict sense; for the cause does not derive from the animal itself, but rather there are other natural movements inherent in animals with which they do not move due to themselves, such as increase, decrease, and respiration, which each animal has while it is at rest and not moving with the movement that is due to itself. The cause of this is what encompasses the animal and many of the things that enter into it—for example, in some cases nourishment; for when nourishment is being concocted, animals sleep, and when it is being distributed [to the various parts] they wake up and move themselves, the first starting-point of

355. Reading τῶν κινούντων.
356. 8.4.
357. 8.5.
358. Reading δὲ.

movement being from the outside, which is why they are not always in continuous movement due to themselves; for the mover is something else, which is itself moving and changing in relation to each thing that moves itself. In all these, however, the first mover and the cause of their self-movement by themselves is moved, but coincidentally; for the body changes its place, so that what is in the body does so as well, and moves itself by means of leverage.[359]

On the basis of these considerations, then, one should be persuaded that if something belongs among the things that are [intrinsically] immovable but are themselves moved[360] coincidentally, it is incapable of causing continuous movement. So, if indeed there must be continuous movement, there must be a primary mover that is not moved even coincidentally, if there is to be, as we have said, an unceasing and undying movement among the beings, and if being itself is to remain in itself and in the same;[361] for if the starting-point remains as it is, the universe must also remain as it is, since it is in continuous relation to the starting-point. (But to be moved coincidentally by itself is not the same as to be moved coincidentally by something else; for to be moved coincidentally by something else belongs even to some starting-points in the heaven, those that are spatially moving with several spatial movements, while to be moved coincidentally by itself belongs only to things that pass away.)

Moreover, if there is in fact something that is always of this sort, moving something while itself remaining immovable and eternal, then the first thing that is moved **260ᵃ1** by it must be eternal as well. Indeed, this is clear also from the fact that there would not be any coming to be, passing away, or change with respect to other things unless something that is in movement causes the movement; for the immovable mover will always move things in the same way and with one movement, seeing that it itself does not change at all in relation to what is moved [by it]. But what is moved by something that, though it is moved, is moved already by what is immovable, because it is related to things now in one way and now in another, will not be the cause of the same movement, but instead, because of being in contrary places or forms, it will produce—being itself in movement—contrary movements in each of the other things and cause it at one time to be at rest and at another time in movement.[362]

It has become evident, then, from what we have said, what the resolution is of the puzzle we raised at the start[363] as to why it is that all things are not either in movement or at rest, or why some are not always in movement and the others always at rest, but instead some are sometimes in movement and sometimes not. For the cause of this is now clear, that some things are moved by an eternal immovable mover, which is why they are always in movement, while some things are moved by a moved and changing mover, so that they too must change. But the immovable mover, as was

359. *MA* 701ᵇ1–32.
360. Reading αὐτῶν κινουμένων.
361. I.e., within the same limits.
362. *GC* 336ᵃ23–ᵇ10, *Met.* 1072ᵃ10–18.
363. 253ᵃ22–24.

said, seeing that it remains simple, selfsame, and in the same state, will move things with a movement that is one and simple.

8.7
Spatial Movement Is the Primary Sort of Movement

This will also be made more evident, however, if we make a different start where these issues are concerned. For we must investigate[364] whether it is possible to be a sort of continuous movement or not, and, if it is possible, what sort it is, and which sort of movement is primary; for if indeed there must always be movement, and if a particular sort is primary and continuous, it is clear that the primary mover causes this sort of movement, which must be one and the same, continuous, and primary.

Since there are three sorts of movement: that with respect to magnitude, that with respect to affection, and that with respect to place, it is this last, which we call "spatial movement," that must be primary. For it is impossible for there to be increase without previous alteration; for what increases is in one way increased by what is like itself, but in another way by what is unlike itself; for contrary is said to nourish contrary. But everything gets added by becoming like to like.[365] It is necessary, then, for this change to a contrary to be an alteration. But if there is in fact alteration, there must be something causing the alteration and making the actively hot from the **$260^{b}1$** potentially hot. It is clear, then, that the mover is not always in the same situation, but sometimes closer, sometimes farther away, from what is altered. But without spatial movement this cannot happen. If, therefore, there must always be movement, there must also always be spatial movement as the primary sort of movement; and if there is a primary sort and a posterior sort of spatial movement, there must always be the primary sort.

Further, the starting-point of all affections is condensation and rarefaction; for heavy and light, soft and hard, hot and cold, seem to be sorts of density or rarity. And condensation and rarefaction are aggregation and disaggregation, in virtue of which substances are said to come to be and pass away. But things that aggregate and disaggregate must change with respect to place. But then the magnitude of what increases and decreases also changes with respect to place.

Further, it will be evident also from the following investigation that spatial movement is primary. For, as in the case of other things, so too in the case of movement, it is said to be primary in many ways. And what is said to be prior is that without which the other things will not exist, while it can exist without them, and there is also priority in time and with respect to substance. So, since there must be movement continuously, and it would exist continuously either if it were continuous or if it were

364. $261^{a}27$–$265^{a}12$.
365. *DA* $416^{a}30$–$^{b}9$.

successive, but more so if it were continuous, and since it would be better for it to be continuous than successive, and we always suppose the better to exist in nature, if it is possible, and it is possible for movement to be continuous (this will be proved later;[366] for now let us assume it), and since no other movement can be continuous except spatial movement, spatial movement must be primary. For there is no necessity for what spatially moves either to increase or to alter, nor of course to come to be or pass away. But none of these other movements can exist without the existence of the continuous movement, the movement that the primary mover causes.

Further, spatial movement is primary in time; for this is the only sort of movement possible for eternal things to move with. [It might be objected,] however, that for each particular thing that comes to be, spatial movement must be the last of its movements; for after a thing comes to be, first alteration and increase occur, while spatial movement is a movement that belongs to things that are already completed. But prior to this there must be something else that is in movement with a spatial movement, which will be the cause even of the coming to be of the things that come to be, though not itself coming to be (for example, what begets is the cause of what is begotten), although it might seem that coming to be is the primary sort of movement, because the thing must first come to be. But though this is so in the case of any particular thing that comes to be, nonetheless there must be something in movement that is prior to the things that come to be, which does not itself come to be, and something else prior to this. And since coming to be cannot be primary (for then all things in movement would admit of passing away), it is clear that none of the movements that are next in order can be prior to spatial movement. By "the ones next in order" I mean increase, then alteration, decrease, and passing away; for all these are posterior to coming to be, so that if not even coming to be is prior to spatial movement, none of the other changes is either.

In general, it appears that what comes to be is incomplete and proceeds to a starting-point, so that what is posterior in relation to coming to be is prior in relation to nature. And spatial movement is the last sort to belong to all the things that are coming to be. That is why, due to a lack of the [requisite] instrumental part,[367] some living things are entirely without movement such as plants and many kinds of animals, while movement belongs to others when they are becoming complete. So, if spatial movement belongs more to the things that have more fully achieved their due nature, this sort of movement would also be prior to the others with respect to substance—both because of the foregoing considerations and because what is moved in a spatial movement departs less from its substance than in any other sort of movement; for it alone does not at all change what it is, while what is altered changes its quality, and what increases and decreases changes its quantity. Above all it is clear that this movement—movement with respect to place—is the movement with which

366. 8.8.
367. Reading τοῦ ὀργάνου.

what moves itself most of all moves in the strict sense. And yet it is this—what moves itself—that we say is the starting-point of things that are moved and of things that are movers and is primary among things moved.

It is evident from these considerations, therefore, that spatial movement is the primary sort of movement. But we must now prove what sort of spatial movement is primary. At the same time, the truth of the assumption we made both just now and previously,[368] that it is possible for there to be a movement that is continuous and eternal, will be evident from this same methodical inquiry.

That none of the other sorts of movement can be continuous is evident from what follows. For all movements and changes are from opposites to opposites—for example, of coming to be and passing away, being and not being are the defining marks; of alteration, they are the contrary affections; and of increase and decrease, they are greatness and smallness, or complete and incomplete magnitude. And the movements to contraries are contrary ones. But what is not always in movement with a certain movement, though it existed previously, must previously have been **$261^{b}1$** at rest. It is evident, then, that what changes will be at rest in the contrary. It is likewise too in the case of changes; for passing away and coming to be, whether unconditional or a particular sort in relation to a particular sort, are opposites. So, if it is impossible for something to be changing in opposite ways at the same time, change will not be continuous, but there will be an interval of time between these opposed changes. For it makes no difference whether contradictory changes are contrary or not (for this is not being used in the argument), as long as they cannot be present in the same thing at the same time. Nor does it make a difference if it is not necessary for the thing to be at rest in the contradictory state, or if change is contrary to rest (for presumably a non-being cannot be at rest, and passing away is change to non-being), but only whether there is a time interval between the opposed changes; for that way the change is not continuous; for even in the previous cases the contrariety [of the states] was not the useful thing; instead, the impossibility of their existing at the same time was.

Nor need one be troubled by the fact that the same thing will have more than one contrary—for example, that movement is contrary to rest and movement to the contrary. We have to grasp only this: that in a way movement is opposed both to the contrary movement and to rest, just as the equal and the moderate are opposed both to what exceeds it and what is exceeded by it, and that it is not possible for opposites, whether movements or changes, to be present at the same time. Further, in the case of coming to be and passing away, it would seem to be entirely absurd if what had come to be must pass away immediately without remaining for any interval of time. So on the basis of these cases one should be persuaded with respect to the others; for it is natural that the same thing holds in all cases.

368. $260^{b}23$, $253^{a}29$.

8.8
Only Circular Spatial Movement Can Be Continuous (1)

We are now in a position to state that it is possible for there to be an unlimited movement that is one and continuous, and that this is circular movement. For everything that is in spatial movement moves either with a circular, a rectilinear, or a mixed movement, so that if one of the former two is not continuous, the combination of both cannot be continuous either. It is clear that what is in spatial movement in a limited straight line is not in continuous spatial movement; for it turns back, and what turns back in a straight line is moved with contrary movements. For with respect to place, contrary movements are the up to the down, the forward to the backward, and the left to the right; for these are the contrarieties of place. But we have previously determined[369] what the one and continuous movement is, that it is the movement of one thing, in one interval of time, and in something undifferentiated with respect to form (for we saw[370] that there were three things: the thing in movement, for example, a human or a god; when it moves, that is, the time; and third, what it is in, and this is place, affection, form, or magnitude). But contraries differ in form and are not one; the differences in place being those we mentioned. And a sign that movement from A to B is contrary to movement from B to A is the fact that they stop or pause each other if they occur at the same time. And likewise in the case of a circle—for example, movement from A [clockwise] to B is contrary to movement from A [counterclockwise] to C (for they stop each other, even if they are continuous and do not turn back, because contraries destroy and prevent each other), while lateral movement is not contrary to upward movement.

It is most of all evident, however, that movement in a straight line cannot be continuous from the fact that what turns back must stop, not only if it is moving in a straight line, but even if it is spatially moving in a circle. For circular spatial movement and moving in a circle are not the same; for at one time what moves in a circle is in connected movement, while at another time it turns back again to the same point from which it began.

One may be persuaded that such movement must come to a stop not only on the basis of perception but also on the basis of argument. We may start with this. For when there are three things, starting-point, mid-point, and end-point, the mid-point is both end-point and starting-point in relation to the other two, and is one in number, but two in account. Further, potentially is distinct from actively. So any point between the extremes of a straight line is potentially a mid-point, but not actively so, unless what is in movement divides the line there by coming to a standstill and starting to move again. In this way the mid-point becomes starting-point and end-point—a starting-point of the later part, and an end-point of the first part

369. 5.4.
370. 227b21–228a6.

(I mean, for example, if in its spatial movement A comes to a standstill at B and then travels again to C). But when its spatial movement is continuous, A cannot either have arrived at or have departed from point B, but can only be there in a now, and not in any interval of time except the one for which that now marks a division: the whole time. But if someone were to grant that it has arrived and has departed, A will always be at a stop when it is in spatial movement; for it is impossible for A to have arrived at and to have departed from B at the same time. It will do so, therefore, at distinct points **262**^{b}**1** of time. Therefore, there will be a time interval between them. So A will be at rest at B, and similarly at the other points; for the same argument will apply to all. But[371] whenever the thing in spatial movement A uses the mid-point B as both end-point and starting-point, it must be at a standstill, because of making it be both, just as one might also do by understanding it that way. But A is the point it has departed from as a starting-point, and C is the one it arrives at when it reaches the end-point and comes to a standstill.

That is why we must also state this in response to the following puzzle. For if line E is equal to line F, and A is in continuous spatial movement from the extremity E to C, and A is at point B at the same time as D is in spatial movement from the extremity F to the other extremity G in a uniform way and with the same speed as A, D will arrive at G before A arrives at C [Fig. 6].

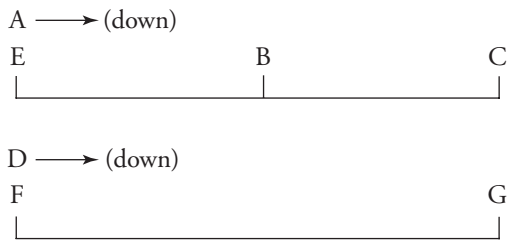

Fig. 6

For what started and departed earlier must arrive earlier. Therefore,[372] A has not arrived at and departed from B at the same time, and that is why it lags behind. For if it does so at the same time, it will not lag behind; on the contrary, to lag behind it must come to a standstill. We must not grant, therefore, that at the time A arrived at B, D was at the same time in movement from F (for if A has arrived at B, its departure will also have occurred, and not at the same time), but A was there in a temporal instant and not in a temporal interval.

In this case, then, where movement is continuous, it is impossible to speak this way. In the case of something that turns back, however, it is necessary to speak this way. For if G spatially moves to D and, turning back, spatially moves back down

371. Reading δὲ.
372. Reading ἄρα.

again, it has used the extremity D as both an end-point and a starting-point, one point as two. That is why it must be at a standstill, and has not arrived at and departed from D at the same time; for then it would be there and not there in the same now. But then we surely cannot state the same resolution over again; for it is not possible to state that G is at D in an instant, and that it has not arrived at or departed from it. For it must arrive at an actual end-point, not a potential one. For points in the middle are potential, while this one is actual, and an end-point from below, a starting-point **263a1** from above—related to the movements [of D], therefore, in the same ways. What turns back along a straight line must, therefore, come to a standstill. Therefore, it is not possible for continuous movement in a straight line to be eternal.

One must reply in the same way to those who pose Zeno's argument and ask whether one must always traverse the half, seeing that these halves are unlimited in number, and it is impossible to traverse what is unlimited. Or to those who pose the same argument in another way and require that during the movement we count the half movement before the whole as we come to each halfway point, so that in traversing the whole it comes about that we have counted an unlimited number. And this is admittedly impossible.

In our first accounts concerned with movement[373] we resolved [this puzzle] due to time having unlimited parts within itself; for nothing absurd follows if in an unlimited time one traverses unlimited distances. And the unlimited is present as much in the length as in the time. But though this resolution is adequate relative to the questioner (for the question is whether in a limited time it is possible to traverse or count unlimited things), relative to the thing and the truth it is not adequate; for if someone sets aside the issue of length, and the question of whether in a limited time one can traverse an unlimited number of distances, and inquires about these questions focusing in on the time itself (for the time is divisible without limit), this resolution will no longer be adequate. But it is the truth that must be stated, precisely the one that we stated in our accounts just now.[374] For if someone divides a continuous line into two halves, he treats one point as two; for he makes it both a starting-point and an end-point. And both counting and dividing in half do this. And if one divides in this way, neither the line nor the movement will be continuous; for continuous movement is over a continuum, and in a continuum there is an unlimited number of halves, not in actuality, however, but in potentiality. But if one makes them actual, one will not make the movement continuous, but rather come to a standstill, which is manifestly precisely what happens when one counts the halves; for one must count **263b1** one point twice; for the end-point of one half will be the starting-point of the other, if one does not count the continuous line as one, but as two halves. So one must reply to the question of whether it is possible to traverse unlimited things either in time or in length that in one way it is and in another way it is not. For in the case of actually

373. 233a21–31, 6.9.
374. 262a19–b21.

unlimited things it is not possible, but in the case of potentially unlimited ones it is possible; for a thing moving continuously has coincidentally traversed unlimited things, while unconditionally it has not; for a line is coincidentally an unlimited number of halves, but its substance—that is, its being—is something else.

It is also clear that unless one posits that the point of time that divides earlier from later always belongs to the later, so far as the thing is concerned, the same thing will both be and not be at the same time, and when it has come to be it will not be. The point, though, is common to both—that is, to both the earlier and the later—and is the same and one in number, though not the same in account (for it is end-point of one and starting-point of the other). But so far as the thing is concerned, it always belongs to its later affection. Let the time be ACB, and the thing D, which is white in time A and not white in time B. In time C, therefore, it is white and not white. For it is true to say that it is white in any time in A, if it was white in all this time, and in B that it is not white. But C is in both times. Therefore, we must not grant that it is white in all of A, but rather at all times except the last now, which is C; and this already belongs to the later period.[375] And if not white was coming to be and white passing away in all of A, not white has come to be and white has passed away at C. So this is the first time at which it is true to say that the thing is white or that it is not white. Otherwise, at the time it has come to be, the white will not exist and at the time it has passed away, it will exist. Alternatively, it must be white and not white at the same time, and, in general, must be and not be.

But if whatever exists without having previously existed must come to be, and if when it is coming to be, it does not exist, time cannot be divisible into indivisible times. For if D was coming to be white in time A, and has at once come to be white and is white in another indivisible but contiguous time B (if D was coming to be white in A, it was not white, but it is white in B), there must be an intermediate coming to be, so that there must also be a time in which D was still coming to be white. The same argument does not apply to those who say that there are no indivisible **264^{a}1** times, but that D has come to be and is white at the extreme point of that same time, with which nothing is contiguous or successive. But indivisible times are successive. And it is evident that if D was coming to be white in the whole time A, there is no time in which it has come to be white and was coming to be white that is greater than the whole time in which it only was coming to be white.

By these and other such arguments, which properly belong to the subject, one may be persuaded. But the result would seem to be the same if we investigate the issue logico-linguistically as follows. For everything that is in movement continuously, if it is not knocked aside by anything else, then precisely the point it arrived at by its spatial movement is the one it was previously spatially moving toward—for example, if something arrived at B, it was spatially moving toward B, and not [merely] when it was in the neighborhood of B, but as soon as it started to move; for why would

375. Reading τὸ ὕστερον.

it be doing so now rather than previously? And similarly in the case of the other [sorts of movement and change]. Suppose, then, that what is in spatial movement from A toward C,[376] when it arrives at C, will again return to A with a continuous movement. At the time, therefore, that it is spatially moving from A toward C, it is also spatially moving to A with a movement that is from C, so that it will have contrary movements at the same time; for movements [in contrary directions] along a straight line are contraries. At the same time, it will also be changing from what it is not [at C]. If, then, this is impossible, it must come to a standstill at C. Its movement, therefore, is not one movement; for a movement that is interrupted by a stop is not one movement.

Further, this is also evident, as a more universal point about all sorts of movement, from the following considerations. For if everything that is in movement is moved with one of the sorts of movement already mentioned and is at rest with the opposite sorts of rest (for we saw that there is no other beyond these), what does not always move with this sort of movement (I mean the ones that are distinct in form, not if some part of the whole is) must previously have been at rest in the opposite state of rest (for rest is privation of movement). If, then, movements in contrary directions along a straight line are contraries and it is not possible to be in contrary movements at the same time, what is in spatial movement from A to C would not at the same time be in spatial movement from C to A. And since it is not in both spatial movements at the same time, but will move with the latter movement, it must be at rest at C; for this is the sort of rest that is opposite to the movement from C [to A]. It is clear, therefore, from these considerations that the movement will not be continuous.

264b1 Further, there is also this argument, which more properly belongs to the topic than the ones mentioned. For suppose that the not white has passed away at the same time as the white has come to be. If, then, the alteration to white and from white is continuous and [the white thing] does not remain [white] for some time, at the same time as the not white has passed away the white has come to be and the not white has come to be; for the time of the three will be the same. Further, if time is continuous, it does not follow that movement is continuous, but that it is successive. And how could the extreme point of contraries—for example, of whiteness and blackness—be the same?

A movement along the circumference of a circle, on the other hand, will be one and continuous; for nothing impossible follows; for what is moving from A will at the same time be moving to A with the same tendency (for what it will arrive at is what it is moving to), but without having contrary or opposite movements at the same time; for not every movement to A is contrary or opposite to a movement from A, but rather they are contrary only if they are along a straight line (for it has contraries with respect to place, such as the extremities of a diameter, since they are furthest apart), and opposite if they are along the same line. So there is nothing to prevent

376. Reading ἐπὶ τὸ Γ.

the [circular] movement from being continuous and without temporal intermission; for circular movement is movement from a point to itself, while movement along a straight line is from one point to another.

Also, circular movement is never in the same things, while rectilinear movement is repeatedly in the same things.[377] It is possible for what repeatedly comes to be now in one thing and now in another to move continuously, but it is not possible for what always comes to be in the same things; for then it would of necessity have contrary movements at the same time. So it is not possible for a thing to move continuously in a semicircle or in any other part of the circumference; for it would of necessity make the same movement repeatedly and change to contrary changes; for this movement does not unite the starting-point and the limit. But circular movement does unite them, and it alone is complete.[378]

It is evident from this division that none of the other sorts of movements can be continuous either; for in all the others we find the same things being traversed repeatedly—for example, in alteration there are the intermediate stages, in quantitative change the intermediate magnitudes, and in coming to be and passing away it is the same way; for it makes no difference whether we make the stages in the change few or many, or whether we add or subtract a stage in between; in either case we find the same things being traversed repeatedly.

It is clear, then, from these considerations that those natural scientists who claim that all perceptible things are always in movement do not speak well; for things must move with one of these sorts of movement, and especially, according to them, alteration; for things are always in flux, they say, and in decay, and further, they speak even of coming to be and passing away as alteration.[379] The present argument, by contrast, states universally that it is not possible to move continuously with any sort of movement except for the circular one, so that nothing can do so either with alteration or with increase.

Let so much be said by us, then, to prove that there is neither unlimited nor continuous change except for circular spatial movement.

377. The things in question are the starting-point and end-point of the movements, since it is the fact that these are united in the case of circular but not rectilinear movement that makes the former continuous and the latter not (264^{b}27–28). To say that a movement is *in* these, however, is not to say that it is between them, but that it has its coming to be in them (264^{b}21–22). Thus what makes circular movement continuous is that its starting-point now comes to be in one thing (one point on the circumference), now in another, and that this is also its end-point (since the two are united), so that these movements are never contraries or opposites.

378. *Cael.* 286^{b}18–23.

379. 187^{a}30.

8.9
Only Circular Spatial Movement Can Be Continuous (2)

And it is clear that circular spatial movement is the primary sort of spatial movement. For every spatial movement, as we said earlier,[380] is either circular, rectilinear, or a mixture of the two. And the first two must be prior to the last; for it is composed of them. And the circular is prior to the rectilinear; for it is simpler and more complete. For a straight line that is unlimited cannot be traversed (for such an unlimited straight line does not exist; and even if it did, nothing would traverse it; for the impossible does not happen, and it is impossible to traverse an unlimited line). But in the case of movement along a limited line, if it turns back, it is composed of two movements, while if it does not turn back, it is incomplete and capable of passing away. And the complete is prior to the incomplete, in nature, in account, and in time, and what is incapable of passing away to what is capable of passing away.[381]

Further, what can be eternal is prior to what cannot be eternal. But in fact circular movement can be eternal, but none of the other sorts, whether of spatial movement or of any other sort whatever, can be so; for rest must occur, and if rest occurs, the movement has passed away.

And it is reasonable that circular movement should be one and continuous, and that rectilinear movement should not; for of movement along a straight line there is a definite starting-point, end-point, and mid-point, which are all contained in it in such a way that there is a point from which what is in movement will start and a point at which it will end (for everything is at rest at the limits, whether the one from which it moves or the one to which), but of movement along the circumference of a circle they are indefinite; for why should any point on the line be a limit more than any other? For each point is alike a starting-point, a mid-point, and an end-point, so that what is in movement is always at the starting-point and at the end-point and **265b1** also never at them. This is why a revolving sphere is in a way both in movement and at rest; for it occupies the same place. The cause of this is that all these features belong to the center-point; for in fact it is starting-point, mid-point, and end-point of the magnitude. So because this point is outside the circumference, there is nowhere for what is in spatial movement to rest as if it has traversed its course (for it is always spatially moving around a mid-point but not to an extreme one), and because of this, the whole is in a way always at rest and remains,[382] and is also always in continuous movement. And there is this reciprocal relation; for in fact because the revolution is also the measure of movements, it must be primary (for everything is measured by what is primary), and because it is primary, it is the measure of the other sorts of movement.

380. 261b29.
381. *Met.* 1050b6–20.
382. Reading διὰ τὸ τοῦτο μένειν.

Further, only circular movement can be regular; for things in rectilinear movement move spatially in an irregular way from the starting-point and to the end-point; for the further everything removes itself from its resting point, the faster is its spatial movement. Circular movement, on the other hand, alone has neither starting-point nor end-point naturally within itself, but rather has them outside.

The fact that spatial movement with respect to place is the primary sort of movement is attested by all those thinkers who have made mention of movement; for they assign the starting-points of movement to things that cause movement of this sort. For aggregation and disaggregation are movements with respect to place, and it is in this way that love and strife move things; for strife disaggregates and love aggregates them.[383] And the [divine] understanding, Anaxagoras says, disaggregates things as the first cause of movement. The same is true of those[384] who mention no cause of this sort but say that things are in movement because of the void. For they too say that nature is moved with movement with respect to place (for movement because of the void is spatial movement and, as it were, in place), and they think that none of the other movements belongs to the primary things but only to their compounds; for they also say that increase and decrease and alteration result from the aggregation and disaggregation of the indivisible bodies. It is the same way too with those[385] who make condensation and rarefaction the cause of coming to be and passing away; for in fact they regulate these by aggregation and disaggregation.

Further, beyond these there are those[386] who make soul the cause of movement; for they say that what moves itself is the starting-point of all things that are in movement, and an animal and every animate thing moves itself with movement with respect to place.

Also, we say that only what is in movement with respect to place is in movement in the strict sense; if it remains at rest in the same place, but increases or decreases or happens to alter, it is in movement in a way, but we do not say that it is in movement unconditionally. **266^{a}1**

That there always was and always will be movement throughout all time, then, what the starting-point of eternal movement is, and further, what the primary movement is, what sort of movement can alone be eternal, and that the primary mover is immovable, has now been stated.

8.10
The Primary Mover

Let us now say that this mover must be without parts and without magnitude, after first determining some prior issues concerning it. And one of these is that no limited thing can cause movement for an unlimited time. For there are three things: the mover, the moved, and third, that in which, time. And these are either all unlimited, all limited, or some are limited—that is, two or one. Let, then, A be the mover, B be the moved, and C the unlimited time. Then let D move some part E of B. Not, then, in a time equal to C; for what is greater takes place in a greater time. So F, the time of the movement, is not unlimited. By adding to D I will use up A, and by adding to E I will use up B. But I will not use up the time by always taking a corresponding amount from it; for it is unlimited. So all of A will move the whole of B in a limited time period of C. It is not possible, therefore, for an unlimited movement to be due to a limited mover.

It is evident, then, that something limited cannot cause movement for an unlimited time. And that, in general, an unlimited capacity cannot be present in a limited magnitude will become clear from the following considerations. For let the greater capacity be the one that always produces an equal effect in a shorter time, as in the case of heating, sweetening, or throwing—in fact, of causing movement in general. What is affected, therefore, must undergo some effect due to the limited magnitude that has an unlimited capacity, and an effect greater than one due to any other; for the unlimited one is greater than any other. But then this cannot take any time at all. For if A is the time in which an unlimited strength heated or pushed something, while in time AB some limited one did so, by continually adding to this strength a **266b1** greater limited one I will eventually have caused the movement in question in time A; for by continually adding a limited quantity I will exceed every definite quantity, and by subtracting, fall short of any definite one in like manner. The limited capacity, therefore, will cause a movement in a time equal to that taken by the unlimited one. But this is impossible. No limited thing, therefore, can have an unlimited capacity.

Neither, moreover, can a limited capacity be present in an unlimited magnitude. And yet it is possible for a greater capacity to be present in a lesser magnitude. True, but a still greater capacity can be present in a greater magnitude. Let AB, then, be an unlimited magnitude. [A part of it] BC, then, has a certain capacity, which in a certain time EF caused movement D. If, then, I take twice BC, it will cause the movement in half the time EF (assuming this to be the proportion), so that it will move in the time FH. Therefore, by always taking in this way I will never exhaust AB, while I will always be taking a smaller part of the given time. The capacity, therefore, will be unlimited; for it exceeds every limited capacity, if, at any rate, every limited capacity must also take a limited time to do what it does (for if such-and-such capacity takes such-and-such time, a greater capacity will cause the movement in a shorter but still definite time that is inversely proportional to the capacity). But a capacity must

always be unlimited—just as a number or a magnitude is—if it exceeds every definite one. This may also be proved in the following way; for if we take a certain capacity, the same in kind as the one in the unlimited magnitude, but this one being in a limited magnitude, it will be commensurable with the limited capacity in the unlimited magnitude. It is clear from these considerations, then, that it is not possible for an unlimited capacity to be present in a limited magnitude, nor for a limited capacity to be present in an unlimited one.

But in the case of spatial movements it will be well to go through a puzzle first. For if everything in movement is moved by something (that is, the ones that do not move themselves), how is it that some will move continuously even when they are not in contact with their mover—for example, projectiles? And if the mover at the same time moves something else, such as the air, which causes movement by being moved, it is likewise impossible for the air to be in movement when the first mover is not in contact with it and moving it—on the contrary, all the things will be in movement at the same time and will stop whenever the first mover stops, even if, like a magnet, it **267^{a}1** makes what it has moved capable of causing movement.

We must, then, say this: that the first mover makes the air, water, or whatever naturally moves or is moved, capable of causing movement. However, this does not at the same time stop moving and stop being moved, but rather it stops being moved at the same time as its mover stops moving it, but it still causes movement, which is why it moves something else contiguous to it, and the same account applies to the latter. But it begins to stop whenever the capacity to cause movement becomes less in each contiguous thing. And it finally stops when the previous one no longer makes the next one a mover, but only something moved. And these things, the mover, on the one hand, the moved, on the other, must stop at the same time, as must the whole movement. This movement comes to be in things that admit of being at one time in movement and at another time at rest, and it is not continuous, though it appears to be; for it occurs either in successive things or in things making contact; for there is not one mover, but movers contiguous to each other. That is why it is in air and in water that this sort of movement occurs—the sort that some people call "reciprocal replacement." But it is impossible to resolve the puzzles raised in any other way than the one that was mentioned. In reciprocal replacement, by contrast, everything would at the same time produce movement and be in movement, and so also stop at the same time. But as things stand it appears that there is one thing in continuous movement. What, then, is it due to? For it is not due to the same thing [that started it moving].

Since among the beings there must be continuous movement, and this is one movement, it must be a certain magnitude's one movement (for what is without magnitude does not move)—it must be of one thing and due to one thing (for otherwise it will not be continuous, but rather a series of movements contiguous to each other and divided). The mover, then, if it is one mover, will cause movement either by being moved or by being immovable. If, then, it is moved, it will itself have to

follow along and undergo change, and at the same time be moved by something, so
267b1 that the series will stop when it will arrive at a movement that is due to something immovable. For this of necessity does not undergo change along with the others, but will always be capable of causing movement (for to cause movement in this way involves no labor[387]), and this movement is regular, either alone or more so than any other; for the mover is never subject to any change. And neither must what is moved
5 be subject to any change in relation to the mover, if its movement is to remain the same. Besides,[388] it is necessary, then, for the mover to be either at the center or on the circumference of a circle; for these are its starting-points. But the things closest to the mover move fastest. And such is the movement of the circumference. That, therefore, is where the mover is.

There is a puzzle as to whether it is possible for anything in movement to cause
10 movement continuously, but not like something that pushes again and again, where [the movement caused is] continuous by being successive;[389] for such a mover must either always push or pull or both, or another thing must receive one from another and again another mover, as was mentioned a moment ago in the case of projectiles,[390] if the air, being divisible, causes movement by one part always being moved after
15 another. In either case there cannot be one movement, but a contiguous series. The only continuous movement, therefore, is that which the immovable mover causes; for it always remains in the same state and so will continuously stand in the same relation to what it moves.

Now that these points are determined, it is evident that it is impossible for the first and immovable mover to have any magnitude. For if it has magnitude, this must be
20 either limited or unlimited. But that there cannot be an unlimited magnitude was proved previously in the *Physics*,[391] and it has been proved just now[392] that a limited magnitude cannot have an unlimited capacity, and that something cannot be moved for an unlimited time by a limited magnitude. But the primary mover causes eternal
25 movement and for an unlimited time. It is evident, therefore, that it is indivisible and without parts, and has no magnitude.

APPENDIX

7.3 (ALTERNATE TEXT)[393]

That all things that are altered are altered due to perceptibles, and that there is alteration only of those things that are intrinsically affected by these, is a fact that we may get a theoretical grasp on from the following considerations. For of the others, it seems that alteration belongs most of all to figures and shapes, and in states, that is, in losing or acquiring them. But it does not exist in these either. Instead, these come to be when something is altered (for example, when the matter is condensed or rarified, heated or cooled); but this is not alteration. For we do not say that the shape [produced] is that from which the shape of the statue is composed, nor that it is the matter from which the candle or the bed is composed, but using a paronym, we say that the first is brazen, the second waxen, and the third wooden. On the other hand, we do say this of the things that undergo alterations; for we say that the bronze is wet, hot, or hard (and not only in this way, but also that the wet and the hard are bronze), speaking homonymously of the matter by using the [name of] the affection. Since, then, that from which the shape and the figure and the thing that comes to be are not things that what is shaped from them is homonymously said to be, while what undergoes alteration is homonymously said to be the affections, it is evident that alteration occurs only in perceptibles. **245b19** 21 23 25 27 29 **246a21** 23

Further, it would also be absurd in another way. For to say that a human being or a house that has achieved its end has been altered is ridiculous, that is, if we say that the completion of the house—its receiving its coping-stone or roof-tile—is an alteration, or that the house is altered when it is coped or tiled. It is clear, then, that alteration is not found in things coming to be. 25 27

Nor does it occur in states. For states are virtues and vices, but every virtue or vice is in [the category of] the relative, just as health is a sort of proportion of hot and cold things, either those within or in relation to what encompasses it. Likewise, beauty and strength are in [the category of] the relative. For they are certain dispositions of the best part in relation to the best good. And by "best" I mean what preserves and disposes according to nature. Since, then, both virtues and vices belong in [the category of] the relative, and these are not comings to be, nor is there a coming to be of them, or any alteration of them at all, it is evident that there is no alteration at all in the case of states. 29 **246b21** 23 25

Nor, then, is there any alteration in the case of the virtues and vices of the soul. For virtue is a sort of completion (for each thing is most complete at the time when it reaches its own proper virtue, and is most in accord with its nature, just as a circular 27

393. Text: S. Maso, C. Natali, and G. Seel (eds.), *Reading Aristotle's Physics VII.3: What Is Alteration?* (Las Vegas, 2012), 28–33.

29 thing is most in accord with its nature when it is most a circle), while vice is the passing away of and departure from these completions.

247ᵃ20 Both the acquisition of virtue and the loss of vice occur because something is altered; however, neither of these is an alteration. But that something is altered is clear. For virtue is a sort of being unaffected or being affected in such-and-such a way, while vice is being affected or being affected contrary to virtue. And virtue of
23 character as a whole happens to be found in pleasures and pains; for pleasure is either in accord with activity or because of memory or due to expectation. If it occurs in
25 activity, the cause is perception, if because of memory or expectation, it is due to the same thing; for pleasure occurs either when we remember how we were affected or when we expect to be affected in the future.

27 But then no alteration belongs to the thinking part of the soul either. For we speak of what has scientific knowledge as belonging mostly in [the category of] the
29 relative. And this is clear; for scientific knowledge does not come to be in those who have a capacity to be moved, but is due to the presence of something; for we acquire
247ᵇ20 scientific knowledge of the universal from the experience of particulars. Nor, then, is the activity [of using scientific knowledge in contemplating something] a coming to be, unless someone were to say that opening one's eyes or touching something was a coming to be; for the activity is like this. But the initial acquisition of scientific knowledge is not a coming to be or an alteration; for it is when the soul comes to a
23 rest and a settling down that someone comes to be a scientific knower and a practically wise person.

Likewise, if someone who wakes up from sleeping, sobers up from drinking, or recovers from sickness did not become a scientific knower, even though before he was not capable of using or activating his scientific knowledge, as soon as he is freed from
25 his restlessness and his thought has come to a rest and a settling down, the capacity to use his scientific knowledge belongs to him. This is the sort of thing, then, that also
27 comes about when scientific knowledge is acquired at the start, a sort of calming of the restlessness and a coming to a stop.

Children, then, are neither capable of learning nor of discerning by means of the
29 perceptual modalities as well as their elders are. For the disturbance and movement [in their souls] is great. But it settles down and comes to rest sometimes due to nature,
248ᵃ26 sometimes due to other causes. But in both cases it happens that something is altered,
27 just as happens in relation to the activity when someone wakes up or sobers up.

It is evident, then, that alteration occurs in perceptibles and in the perceptual part
248ᵇ26 of the soul, and in nothing else except coincidentally.

On the Heavens

BOOK 1

1.1
The Completeness of the Universe

It is evident that scientific knowledge about nature is, in pretty much its largest part, concerned with bodies and magnitudes, their affections and movements, and further, **268ª1**
with the starting-points, as many as there may be of this sort of substance; for of the things composed by nature, some are bodies and magnitudes, some have body and magnitude, while others are starting-points of things that have these. 5

The continuous, then, is what is divisible into things that are themselves always divisible, and a body is what is divisible in all ways. A magnitude continuous in one dimension is a line, in two dimensions a plane, in three dimensions a body. And beyond these there is no other magnitude, because the three dimensions are all the dimensions there are, and so in three ways is in all ways. For, as the Pythagoreans also 10
say, the universe and all things are defined by [the number] three, since end-point, mid-point, and starting-point have the number of the universe, and their number is the triad.[1] That is why, having taken these from nature, as if they were its laws, we make use of this number even in the worship of the gods.[2] And we assign labels too 15
in this way; for we use both of two things and both of two people, but we do not use all, but rather three is the first number with reference to which we use the latter mode of address. And in these domains, as was said, we do so because of following the lead of nature itself.

So, since all things, the universe, and the complete do not differ from each other 20
with respect to form, but rather, if indeed they do differ, it is with respect to matter and the things of which they are said, body alone among the magnitudes would be complete; for it alone is defined by [the number] three, and this is All.

Being divisible in three dimensions, body is divisible in all, while of the others, one lot is divisible in one, the other lot in two; for as it is with the number they attain, 25
so it is too with their divisibility and continuity; for one is continuous in one dimension, another in two, and this sort in all. All magnitudes, then, that are divisible are

* Translated by C. D. C. Reeve. Text: P. Moraux, *Aristote: Du Ciel* (Paris, 1965).

1. *Met.* 985ᵇ23–986ª3.

2. A number of cult actions in Greek religion had to be repeated three times.

also continuous. But whether all that are continuous are also divisible is not yet clear on the basis of the present considerations.

One thing, however, is clear: it is not possible to transition to another kind of magnitude, as we transition from length to surface, and to body from surface; for magnitude of this sort would no longer be complete; for it is necessary that the end of the transition comes about in accord with a deficiency. But what is complete cannot be defective; for it is [complete] in all ways.

Bodies, then, that are in the form of parts are each, according to this account, complete this sort [of complete]; for each has all the dimensions. But each one is determined by contact with what is neighboring. That is why each of the bodies is in a way many. But the universe, of which these are parts, is necessarily complete, and, as its name signifies, in all ways, not in one way so and in another not.

1.2
Primary Body (Ether)

As regards the nature of the universe, whether it is unlimited in magnitude or its total mass is limited must be investigated later.[3] Now, though, we will speak about the parts of it with respect to form, having made the following our starting-point:

For we say that all natural bodies and magnitudes are intrinsically capable of moving with respect to place; for nature, we say,[4] is the starting-point of movement for them. All movement with respect to place—which we call "spatial movement"—is either rectilinear or circular or a mixture of these; for these two are the only simple movements. And the cause of this is that these magnitudes are also the only simple ones: the straight line and the circumference. Circular movement is movement around the center, rectilinear is movement up and down. By "up" I mean the one away from the center, by "down," the one toward the center. So it is necessary for all simple spatial movement to be away from the center, toward the center, or around the center. And this seems to follow in accord with the account at the start;[5] for both body and its movement found completion in [the number] three.

Since of bodies some are simple and others composed of these (by "simple" I mean those that have their starting-point of movement in accord with nature—for example, fire and earth, the various forms of these, and things of the same kind as these), it is necessary that their movements too are in some cases simple and in others some sort of mixture—simple in the case of the simple bodies, mixed in the case of the composite ones, but in their case movement is in accord with the predominant component.

3. 1.5–7.
4. *Ph.* 192ᵇ20–23.
5. 268ª6–ᵇ10.

If indeed, then, there is simple movement, and circular movement is simple, and the movement of a simple body is simple movement, and simple movement is movement of a simple body (for if the body is composite, its movement will be in accord with the predominant component), it is necessary for there to be some simple body that, in accord with its own nature, naturally moves spatially in a circle; for by force it is possible for its movement to be that of another, distinct body, but in accord with nature it is impossible, if indeed the movement in accord with nature of each of the simple bodies is a single one.

Further, if movement contrary to nature is contrary to movement in accord with nature, and if one thing has one contrary, then, it is necessary, since circular movement is simple, if it is not going to be in accord with the nature of the spatially moving body, that it is contrary to its nature. If, then, fire or something else of this sort is the thing spatially moving in a circle, its spatial movement in accord with nature will be contrary to the circular. But one thing has one contrary, and spatial movements up and spatial movements down are contrary to each other. If, on the other hand, it is some distinct body that is the one spatially moving in a circle contrary to nature, there will be some other movement for it that is in accord with nature. But this is impossible; for if it is the spatial movement up, the body will be fire or air, and if it is down, water or earth.

But then too it is necessary for the spatial movement in question to be primary. For the complete is prior in nature to the incomplete, and the circle is one of the complete things, while no straight line is; for an unlimited one is not complete (for [to be complete (*teleion*)] it would have to have a limit, that is, an end (*telos*)) and neither is any of the limited ones (for all limited ones have something outside them; for any of them can be extended). So if indeed the movement that is prior is that of a body that is prior in nature, and circular movement is prior to rectilinear, and rectilinear movement is movement of the simple bodies (for example, fire spatially moves in a straight line upward and earthen bodies in a straight line toward the center), it is necessary for circular movement to be the movement of some simple body too; for the spatial movement of mixed bodies, we have said,[6] is in accord with the simple body that is the predominant one in the mixture.

On the basis of these considerations, then, it is evident that there is some natural corporeal substance beyond the ones composed here, more divine and prior to all these. And further, if one were to assume that all movement is either in accord with nature or contrary to nature, and that what is contrary to nature for one thing is in accord with nature for another thing (for example, as is the case with upward and downward movements, which are contrary to nature and in accord with nature for earth and fire, respectively), it would necessarily follow that circular movement too, since it is contrary to nature for these, is in accord with nature for something else. **$269^{b}1$**

6. $269^{a}1–2$.

In addition, if circular spatial movement is in accord with nature for anything, it would clearly be some simple and primary body which in accord with nature spatially moves naturally in a circle, as fire does upward and earth downward. If, on the other hand, the things that spatially move in a circle perform the all-around spatial movement contrary to nature, it would be a wondrous and altogether unreasonable thing for this movement alone to be continuous and eternal, though it is contrary to nature; for it is evident in other cases that what is contrary to nature passes away fastest. So if indeed the thing spatially moving [in a circle] is fire, as some people say,[7] this movement will be no less contrary to nature for it than movement downward; for we see that the movement of fire is the rectilinear one away from the center.

This is why a person who makes his deductions on the basis of all these considerations would be persuaded that there is some body beyond the ones around us here, separate from them, and having a nature that is more estimable to the extent that it stands further off from those here.

1.3
Primary Body Is Exempt from Alteration and Passing Away

Since some of the things that have been said are being assumed while others have been demonstrated, it is evident that not all body has lightness or heaviness. But we must set down what we mean by "the heavy" and "the light"—now in a way that is sufficient for our present needs, though later in a more exact one,[8] when we investigate their substance. Let heavy, then, be what naturally moves spatially toward the center, light, away from the center; heaviest, what sinks below all the downward-moving bodies, lightest, what rises above all the upward-moving ones.

It is necessary, then, for everything that moves spatially down or up to have lightness, heaviness, or both—though not in relation to the same thing; for things are heavy and light in relation to each other—for example, air is light in relation to water, while water is so in relation to earth. But the body that spatially moves in a circle cannot possibly have heaviness or lightness; for neither in accord with nature nor contrary to nature does it admit of moving toward the center or away from the center. For in accord with nature, rectilinear spatial movement does not pertain to it; for the movement of each of the simple bodies is, as we saw,[9] one movement, so that the body that spatially moves in a circle will be the same as one of the bodies spatially moving in this way. On the other hand, if it is moved contrary to nature, then if downward movement is contrary to nature, upward will be in accord with nature, and if upward is contrary to nature, downward will be in accord with nature; for we

7. Thales A17a DK; Anaximander A21; Anaximenes A7, A12; Heraclitus B30; Parmenides B12; Anaxagoras A84; Plato, *Timaeus* 40a, *Epinomis* 982a–b.
8. 4.1–4.
9. 269ᵃ8–9.

posited[10] that, of contrary movements, if for something one movement is contrary to nature, the other is in accord with nature.

Since, however, the whole [body] and the part—for example, all of earth and a small clod—spatially move in accord with nature to the same place, it follows, first, that the body [that spatially moves in a circle] has neither lightness nor heaviness (for otherwise it would be capable of spatially moving either toward the center or away from the center in accord with its own nature). Next, it follows that it cannot be moved with respect to place by being hauled either up or down; for it does not admit of moving, either in accord with nature or contrary to nature, with a movement other than its own, either itself or any of its parts; for the same argument applies to whole and part.

It is equally reasonable to suppose about this body that it is incapable of coming to be and passing away, incapable of increase, and incapable of alteration, because everything that comes to be comes to be from its contrary and from an underlying subject, and passes away similarly—from an underlying subject, because of a contrary, and to a contrary, as was said in our first accounts.[11] And the spatial movements of contraries are also contrary. If, then, this body can have no contrary, because there cannot in fact be a movement contrary to spatial movement in a circle, nature seems to have correctly removed from among the contraries the body that was going to be incapable of coming to be and passing away. For coming to be and passing away happen in the realm of contraries.

But then too everything that increases, increases because of something of the same kind being added to it and dissolving into its matter. But there is none from which this body has come to be.

But if it is not capable of either increase or passing away, the same thinking leads us to suppose that it is not capable of alteration either. For alteration is movement with respect to quality, and qualitative states and dispositions—for example, health and disease—do not come about without change with respect to the affections. But as it regards all natural bodies that change with respect to an affection, we see them to be subject both to increase and decrease—for example, the bodies of animals and plants and their parts, and also those of the elements. So if indeed the body in circular movement does not admit of either increase or decrease, it is reasonable for it to be incapable of alteration as well.

Why, then, the primary body is eternal and not subject to increase or decrease, but rather incapable of aging, incapable of alteration, and unaffectable, is—provided our assumptions are convincing—evident from what has been said. **$270^{b}1$**

It seems too that the argument attests to the things that appear to be so, and the things that appear to be so attest to the argument; for all human beings have a supposition about the gods, and all—both barbarians and Greeks, as many as acknowledge

10. $269^{a}32–34$.
11. *Ph.* 1.7–9.

gods at all—assign the highest place to the gods, on the assumption, clearly, that immortal is closely linked with immortal; for any other way is impossible. If indeed, then, there is something divine, as indeed there is, the things just now said about the substance that is primary among the bodies were correctly said.

But this result also follows sufficiently enough through perception, at any rate for (one might almost say) merely human conviction; for in all of past time, according to the record people have handed down one to another, nothing appears to have changed either in the whole of the outermost heaven[12] or in any of the parts proper to it.

And it seems that the name too has been handed down even to the present time by the ancients, who conceived of it in the very way we ourselves speak of it; for one must acknowledge that the same beliefs return to us not once or twice but an unlimited number of times.[13] That is why, on the supposition that the primary body is something distinct, beyond earth, fire, air, and water, they gave the name *aithêr* ("ether") to the uppermost place, positing a name for it from the fact that, throughout eternal time, it is running always (*thein aei*). Anaxagoras, on the other hand, does not use this name correctly; for he uses *aithêr* in place of [what he should call] "fire."[14]

It is also evident from what has been said why the number of what are called "simple bodies" cannot be greater; for it is necessary for the movement of a simple body to be simple, and we say that the following are the only simple movements: circular and rectilinear, and the two parts of the latter, the one away from the center, the other toward the center.

1.4
Circular Movement Has No Contrary

That there is no other spatial movement contrary to spatial movement in a circle is a conviction one may obtain from many sources.

First, one assumes the straight line to be opposed above all to the circumference; for concave and convex seem to be opposed not only to each other but also, when they are coupled and taken as a composite, to the straight line.[15] So if indeed there is a contrary movement, it is above all necessary for what is contrary to movement in a circle to be rectilinear movement. But rectilinear movements are opposed to each other because of their places; for up-down is at once a difference of place and a contrariety.

12. The outermost (or, looking inward, the first) heaven is the sphere of the fixed stars.
13. *Mete.* 339ᵇ27–30, *Met.* 1074ᵃ38–ᵇ14.
14. B2 DK.
15. Begin with two equal semicircles, S_1 and S_2. Nest S_1 inside S_2. Notice that the "concave" S_1 and the "convex" S_2, which seem to be opposed, have now been joined together. But both clearly stand opposed to their common straight diameter. And that opposition remains when S_1 is flipped 180° along that diameter, so as to form the circumference of a circle with S_2.

Next, if someone supposes that the very same argument that applies to rectilinear applies also to spatial movement along a circumference—for example, that spatial movement from A to B is contrary to that from B to A [Fig.1]—

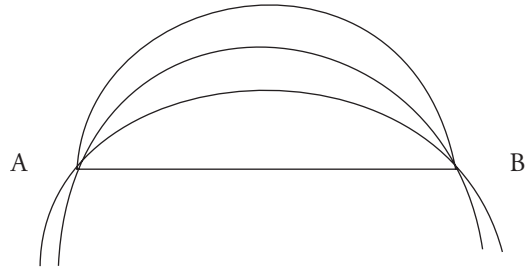

Fig. 1

it is [in fact] the rectilinear he is speaking of; for it is limited, but there would be an unlimited number of circumferential lines through the same points.

It is the same too in the case of one of the two semicircles—for example, from C to D and from D to C [Fig. 2];

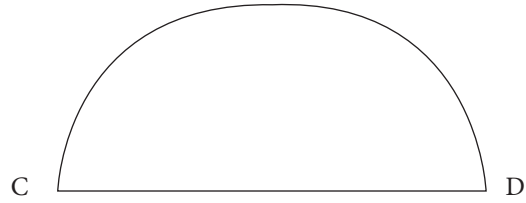

Fig. 2

for it [the spatial movement] is the same as along the diameter, since we always suppose the distance between each pair of points to be a straight line.

And it is the same even if one constructed a circle and posited that the spatial movement along one semicircle was contrary to that along the other—for example, that along the whole circle, the spatial movement along semicircle G from E to F is contrary to that along semicircle H from F to E [Fig. 3].[16]

16. When the semicircles G and H are separate, the spatial movement from E to F is distinct from the one from F to E, because they are to and from distinct places, and so are distinct for the same reason that the corresponding rectilinear ones would be. But when the semicircles are joined (as in Fig. 4), E and F are both starting-point and end-point of the same spatial movement. The Bekker text of the following paragraphs is reorganized as indicated.

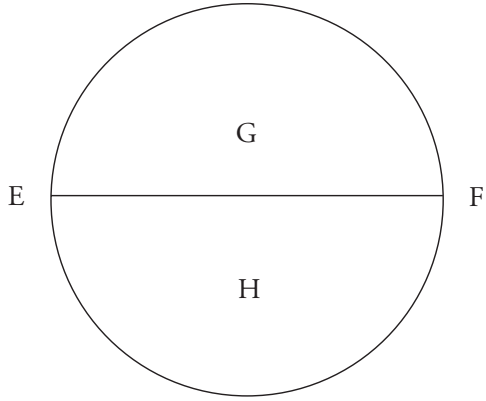

Fig. 3

Even if these were contraries, however, it in no way follows that the spatial move-
23 ments along the whole circle are contraries. For they will be on the same circular path, because it is necessary for what spatially moves in a circle, wherever it starts
25 from, to return to all the contrary places alike (the contrarieties of place are up and down, front and back, right and left), and the contrarieties of spatial movement are
28 in accord with the contrarieties of place.

19 But then neither is spatial movement in a circle from A to B contrary to that from A to C [Fig. 4];

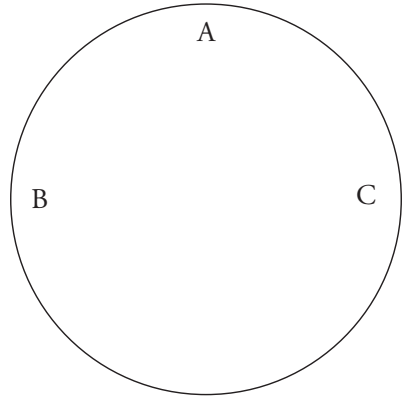

Fig. 4

for the movement is from the same and to the same, but a contrary spatial movement was defined as from a contrary to a contrary.[17]

And even if spatial movement in a circle were contrary to spatial movement in a circle, one or the other would be pointless. For if they were equal, there would be no movement of them, while if one of the movements did the mastering, the other would not exist. So if there were two bodies, one of the two, in not moving with its own movement, would be pointless; for we say that a shoe is pointless if it is not being worn as a shoe. The god and nature, however, make nothing pointlessly.

1.5
Primary Body Is Not Unlimited

But since we are now clear about these matters, we must investigate the remaining ones, and first whether there is an unlimited body, as most of the ancient philosophers thought,[18] or whether this is an impossibility; for its being the former way or the latter way makes no small difference—but rather absolutely all the difference—as regards getting a theoretical grasp on the truth; for this has been and is the starting-point of pretty much every disagreement among those who have made some pronouncement about nature as a whole, if indeed even a small initial deviation from the truth later on multiplies itself ten thousand times. For example, if someone said there is a smallest magnitude, this person, by having introduced the smallest one, would have upset the greatest things in mathematics. The cause of this is that the starting-point is greater in capacity than in magnitude, which is why what is small at the start becomes immensely great at the end. But the unlimited has both the capacity of a starting-point and, in quantity, the greatest one. So there is nothing absurd or unreasonable in the fact that the difference that stems from the assumption that there is an unlimited body is a wondrous one. That is why we must speak about it, taking it up from the start.

It is necessary, then, for every body to be either simple or composite, so that the unlimited one too will be either simple or composite. But it is also clear, surely, that if the simple ones are limited, it is also necessary for the composite one to be limited; for what is composed of things that are limited in both number and magnitude is limited in both number and magnitude; for it is as great as what it is composed of.

It remains, therefore, to see whether any of the simple bodies can be unlimited in magnitude, or whether this is impossible. When we have discussed the primary one among the bodies, then, let us investigate the remaining ones in the same way.

That it is necessary for the body that spatially moves in a circle to be limited in its entirety is clear from the following:

17. Even though B and C have distinct labels, spatial movements in the same circle all have the same starting-points and end-points, and so cannot be contraries.

18. Anaximander A11, B2 DK; Anaximenes A7; Anaxagoras B1, B2; Melissus B3; Democritus A37.

For if the body moving spatially in a circle is unlimited, the radii produced from the center will be unlimited. But the interval between unlimited radii is unlimited—
30 by an "interval between lines" I mean that outside of which no magnitude in contact with the lines can be found. It is necessary, then, for this interval to be unlimited; for the interval between limited lines will always be limited. Further, it is always possible
272ᵃ1 to take [an interval] greater than [any] given one, so that just as we say that number is unlimited, because there is not a greatest, the same argument also applies to the interval. If, then, it is not possible to traverse the unlimited, and if, of an unlimited body, it is necessary for the intervals to be unlimited, it could not possibly be moving
5 in a circle. But we see the heaven revolving in a circle, and we have also determined by argument that movement in a circle belongs to a certain thing.

Further, if you subtract a limited time from a limited time, it is necessary for the remainder to be limited as well and to have a starting-point. But if the travel time has a starting-point, there is also a starting-point of the movement, and so of the
10 magnitude that has been traveled. And the same applies to the other cases too.

Let, then, the line ACE be unlimited in one direction, E, and the line BB be unlimited in both directions [Fig.5].

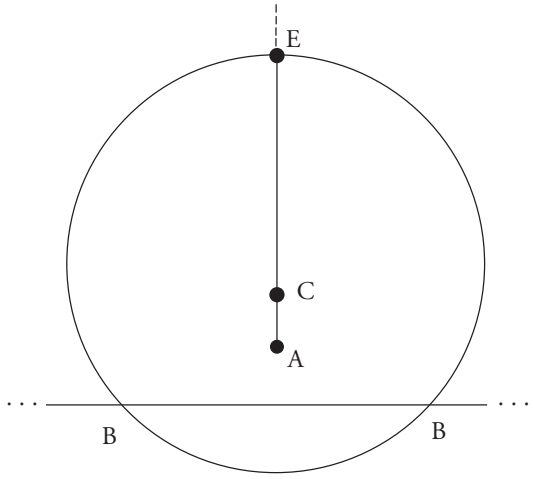

Fig. 5

If, then, the line ACE inscribed a circle with C as its center, ACE will at some time spa-
15 tially move in a circle while cutting BB for a limited time; for the entire time in which the heaven spatially moved in a circle is limited. Therefore, the time subtracted from this, in which it was doing the cutting, is limited as well. Therefore, there will be a starting-point at which ACE first cuts BB. But this is impossible. Therefore, it is not possible for the
20 unlimited to revolve in a circle. So neither could the cosmos,[19] if it were unlimited.

19. I.e., the primary (or outermost) heaven.

Further, it is also evident from the following considerations that it is impossible for the unlimited to move. For let the limited line A be spatially moving past the limited line B. It is necessary, then, for A to get clear of B, at the same time as B gets clear of A; for the extent to which one overlaps the other is the same as that to which the other overlaps the one. If, then, both were moving in contrary directions, they would get clear of each other faster, while if one were spatially moving past one remaining at rest, they would do so more slowly, provided the one spatially moving past the other is moving at the same speed.

But this at least is evident, that it is impossible to traverse an unlimited line in a limited time. Therefore, it must be in an unlimited one. This was proved previously in the discussions concerning movement.[20] And it makes no difference at all whether the limited line is spatially moving past the unlimited one, or the unlimited one past it; for whenever the one passes the other, the other passes the one, whether it is moving or unmoving, except that they will get clear of each other faster if both are moving. And yet sometimes there is nothing to prevent a moving line from passing one at rest faster than one moving in a contrary direction, if one has made both the lines moving spatially in contrary directions move slowly, but the one passing the one at rest moves spatially much faster than them.

272^{b}**1**

It is no impediment to the argument, then, that one line is moving past a line that is at rest, since it is possible for a moving A to pass a moving B more slowly [than if it were immobile]. If, then, the time in which a limited moving line gets clear [of an unlimited one] is unlimited, it is necessary for the time in which an unlimited one moves past a limited one to also be unlimited. It is impossible, therefore, for the unlimited to move as a whole; for if it moves even the smallest distance, it is necessary for it to do so in an unlimited time. But then the heaven as a whole does go around and revolve in a circle in a limited time, so it goes around any line within it—for example, the limited line AB[21] [Fig. 6]:

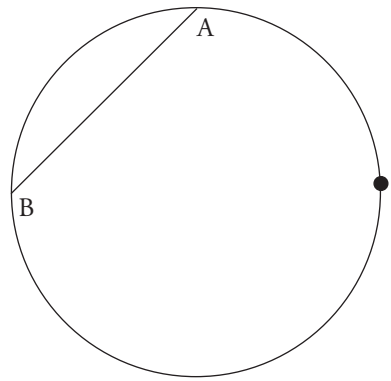

Fig. 6

20. *Ph*. 5, 6, and 8.
21. Either the chord AB or the corresponding arc.

It is impossible, therefore, for the body moving in a circle to be unlimited.

Further, just as a line, insofar as it is a limit, cannot possibly be unlimited (or rather, if indeed it is, it is in length), a plane too, insofar as it is a limit, cannot be unlimited, and, if it is a definite one, it cannot be unlimited in any way—for example, a square, a circle, or a sphere cannot be unlimited, any more than a foot-long line can be. If, then, neither a sphere nor a circle can be unlimited, and if there were no circle, there would be no spatial movement in a circle, and similarly if there were no unlimited circle, there would be no unlimited spatial movement in a circle, then if there were no unlimited circle, there would be no unlimited body moving in a circle either.

Further, if C is the center, the line AB is unlimited, E is an unlimited line at right angles to it, and CD a moving line, CD will never get clear of E, but will always be in a situation like that of CE, since it cuts E at F [Fig. 7].

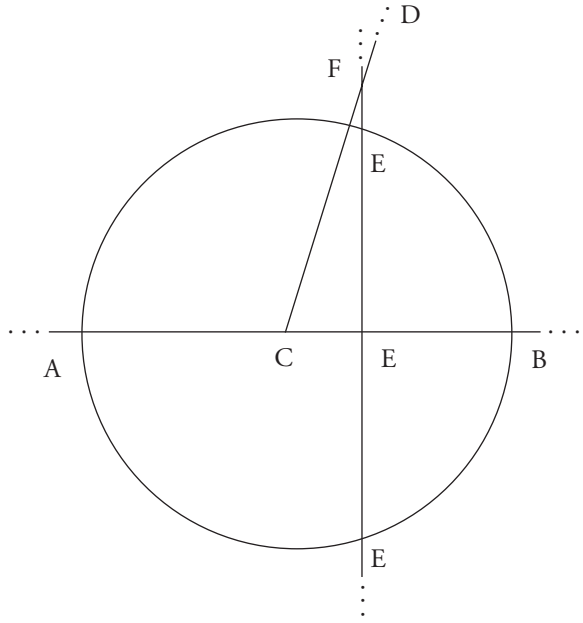

Fig. 7

The unlimited line, therefore, will not go around the circle.

Further, if the heaven is unlimited, and moves in a circle, it will have traversed the unlimited in a limited time. For let the heaven when remaining at rest be unlimited, and another heaven moving within it be of equal magnitude.[22] So if the latter, being unlimited, has indeed gone around in a circle, it has traversed an unlimited equal to itself in a limited time. But this, we saw,[23] is impossible.

22. Assuming that one unlimited body can fit exactly inside another, with the one at rest being what the other is moving relative to.
23. *Ph*. 6.7.

One can also state it conversely, that if the time in which it has revolved is limited, **273a1**
it is necessary for the magnitude traversed to also be limited. But it has traversed a magnitude equal to itself. Therefore, it too is limited.

That, then, the body moving in a circle is neither unending nor unlimited, but 5
has an end, is evident.

1.6
No Element Is Unlimited

Moreover, neither what spatially moves toward the center nor what moves away from the center will be unlimited:

For spatial movements upward and downward are contraries, and contrary ones are to contrary places. And if one of two contraries is definite, the other will be definite too. But the center is definite; for wherever the body that sinks down spa- 10
tially moves from, it cannot go further than the center. Since, then, the center is definite, the upper place must also be definite. But if the places are definite, that is to say, limited, the bodies will also be limited. Further, if up and down are definite, it is necessary for what is intermediate to be definite too. For if it is not definite, 15
movement would be unlimited. But that this is impossible was proved previously.[24] Therefore, the center is definite, so that a body that is in it, or that can come to be in it, is definite as well. Moreover, the bodies spatially moving upward or downward can come to be in it; for the one naturally moves away from the center, the other toward 20
the center. From these considerations, then, it is evident that there cannot possibly be an unlimited body.

Also, in addition to these, if there is no unlimited heaviness, none of these bodies could be unlimited either; for it is necessary for the heaviness of an unlimited body to be unlimited too. (The same argument will also apply in the case of lightness; for if there is an unlimited heaviness, there will be unlimited lightness as well, if what rises 25
above is unlimited.) This is clear from the following:

For let heaviness be limited, and take an unlimited body AB, of weight C. Then, let the limited magnitude BD be subtracted from the unlimited body, and let its weight be E. E will then be smaller than C; for the weight of the smaller magnitude 30
will be smaller. Let the smaller, then, taken as many times as you like, measure out the greater, and, as the smaller weight is to the greater, let BD be to BF; for it **273b1**
is possible to subtract as much as one likes from the unlimited. Therefore, if the magnitudes are proportional to the weights, and the smaller weight is of the smaller magnitude, the greater would also be of the greater one. Therefore, the weight of the limited one and of the unlimited one will be equal. 5

24. 272a21–b17.

Further, if the greater weight is of the greater body, the weight of GB[25] will be greater than that of FB, so that the weight of the limited will be greater than that of the unlimited. Or the weight of unequal magnitudes will be the same; for the unlimited is unequal to the limited.

And it makes no difference whether the weights are commensurable or incommensurable; for the same argument will apply even if they are incommensurable—for example, if E, taken three times in measuring C, exceeds it; for three times the whole weight of the three magnitudes BD[26] will then be greater than that of C. So there will be the same impossibility.

Further, we can however assume them to be commensurable; for it makes no difference whether one starts from the weight or from the magnitude—for example, if weight E is taken to be commensurable with C, and a magnitude, BD, of weight E is subtracted from the unlimited, then as weight is to weight, BD will be to some other magnitude, BF; for if the magnitude is unlimited, it is possible to subtract as much as one likes; for if this is so, both the magnitudes and the weights of the things will be commensurable with each other.

Nor indeed will it make any difference to the demonstration whether the magnitude has its weight uniformly or non-uniformly distributed; for it is always possible to take bodies of equal weight to BD, subtracting from the unlimited or adding whatever one wishes.

So it is clear from what has been said that the weight of an unlimited body will not be limited. Therefore, it is unlimited. If, then, this is impossible, it is also impossible for there to be any unlimited body.

But that it is impossible for there to be any unlimited weight is evident from the following. For if a certain weight moves a certain distance in a certain time, a yet greater one will move the same distance in a shorter time, and the proportion the weights have, the times will have in reverse—for example, if half the weight moves in
274ᵃ1 a certain time, twice the weight will do so in half the time. Further, a limited weight will traverse any limited distance in a certain limited time. Therefore, it is necessary on the basis of this that if there is an unlimited weight, it must on the one hand move (insofar as it is as great as a limited one plus yet more), but on the other hand not move (insofar as it must move in proportion to the excess, though in the reverse way: the greater weight in the shorter time).—But there is no ratio of the unlimited to the limited, while there is one of the shorter time to the greater limited time. But perhaps [as the weight increases, it moves] in an ever shorter time. But there is no shortest time. Nor, if there were, would it be of any benefit; for some other greater limited weight could have been taken in the same ratio in which the unlimited one stood to

25. A limited sub-part of the unlimited body greater than FB (previously, BF), which is unlimited.

26. BD serves as a unit E for measuring weight.

the other. So the unlimited weight would move the same distance in the same time as the limited one. But this is impossible.

Moreover, it is surely necessary, if indeed an unlimited weight can move in any limited time, for there to be another limited weight that will move a certain limited distance in the same time.

It is impossible, therefore, for there to be an unlimited heaviness, and similarly there cannot be unlimited lightness either. Therefore, bodies having unlimited heaviness or lightness are also impossible.

1.7
No Body Is Unlimited

That there can be no unlimited body is clear through getting a theoretical grasp on the particular [simple bodies] in the foregoing way, and by a universal investigation not only in accord with the arguments in our discussions concerning the starting-points[27] (for there we previously determined in universal terms in what way the unlimited exists and in what way it does not exist), but now also in another way. After this we must investigate whether, even if the body of the universe is not unlimited, it may nonetheless be enough for there to be several heavens; for perhaps someone might be puzzled about whether there is anything to prevent there being others, more than one, composed just like the cosmos around us, though of course not an unlimited number. First, though, let us speak in universal terms about the unlimited.

It is necessary, then, for every body to be either unlimited or limited, and if unlimited, either entirely uniform or non-uniform, and if non-uniform, either composed of a limited number of forms or of an unlimited number. That it cannot then be composed of an unlimited number is clear, if one will allow our first assumptions to stand. For since the primary movements are limited, it is necessary for the forms of the simple bodies to also be limited. For the movement of a simple body is simple, and the simple movements are limited in number, and it is necessary for every natural body to have movement.

On the other hand, if indeed the unlimited is to be composed of a limited number [of forms], it is necessary for each of the parts to be unlimited—I mean, for example, water or fire. But this is impossible; for it has been proved[28] that neither heaviness nor lightness is unlimited.

Further, it is necessary for their places to also be unlimited in magnitude, so that the movements of all of them must be unlimited as well. But this is impossible, if we are to posit that our first assumptions are true, and that what spatially moves

27. *Ph*. 3.4–8.
28. 1.6.

downward cannot possibly move without limit, nor, in accord with the same argument, can what spatially moves upward. For it is impossible for what cannot have come to be to be coming to be, alike in quality, quantity, and in place. I mean that if it is impossible for a thing to have come to be white, or a cubit long, or in Egypt, it is also impossible for it to be coming to be any of these things. Therefore, it is impossible even to spatially move toward a place where no spatially moving thing is capable of arriving.

Further, even if they are dispersed, it might nonetheless still be thought possible for what is composed of all its particles[, for example,] fire,[29] to be unlimited. But body, we saw,[30] is what has extension in all ways. So how could there possibly be several dissimilar bodies, each of which is unlimited? For each must be unlimited in all ways.

But then neither can the unlimited body be entirely uniform. For, first, there is no other [rectilinear] movement besides these. It will, then, have one of these. But if this is so, it will follow that there will be either unlimited heaviness or unlimited lightness. But then the body that spatially moves in a circle cannot be unlimited either. For it is impossible for the unlimited to spatially move in a circle; for there is no difference between saying this and saying that the heaven is unlimited, and this has been proved to be impossible.

But then it is in fact not possible for the unlimited to move at all. For it will move either in accord with nature or by force. And if by force, there will also be the movement that is in accord with nature for it, so that there will be another place of equal size toward which it will spatially move. But this is impossible.[31]

That it is impossible in general for the unlimited to be affected in any way by the limited, or to affect the limited, is evident from the following. For let A be unlimited, B limited, C the time in which it moves something or is moved. If, then, A is heated, pushed, or affected in some other way by B, or is moved in any way in the time C, let D be smaller than B, and let the smaller move a smaller in an equal time. Let E be what has been altered by D. Then, as D is to B, E will be to some limited quantity. Let, then, the equal alter an equal in an equal time, the smaller a smaller in an equal one, and the greater a greater one—the later being greater precisely in the same proportion as the greater [mover] to the smaller one. Therefore, the unlimited will not be moved by any limited thing in any time; for a smaller thing will be moved by another smaller one in an equal time, and what is proportional to it will be limited; for the unlimited stands in no ratio to the limited.

But then neither will the unlimited move the limited in any time. For let A be unlimited, B limited, and C the time in which it does so. Then D will move something smaller than B in C; let it be F. What BF as a whole is to F, then, let E stand

29. Retaining πῦρ.
30. 268a7.
31. Since if it were unlimited, it would already have occupied all of place prior to moving.

in this ratio to D. Then E will move BF in time C. Therefore, the limited and the unlimited will cause an [equal] alteration in an equal time. But this is impossible; for it was assumed that the greater does so in a shorter time. Whatever time is taken, the result will be the same, so that there will be no time in which the unlimited will move something. But then it cannot move something or be moved in an unlimited time either; for it has no limit, while affecting and being affected do.

Nor, then, can the unlimited be affected by the unlimited in any way. Let A and B be unlimited, and CD the time in which B was affected by A. Then, since the whole of B was affected, E, which is a part of the unlimited, will not be affected to the same extent in an equal time. For let it be assumed that the smaller is moved in a shorter time. Let E have been moved by A in D. Then what D is to CD, E is to some limited part of B. Therefore, it is necessary for this to be moved by A in time CD. For let it be assumed that the greater and smaller things will be affected in a longer and a shorter time by the same thing, when they are determined in proportion to the time. Therefore, there is no limited time in which the unlimited can be moved by the unlimited. Therefore, it must be in an unlimited one. But an unlimited time does not have an end, while what has been moved does have [an end of its movement].

Therefore, if every perceptible body has the capacity to affect, or be affected, or both, an unlimited body cannot be perceptible. Moreover, whatever bodies are in a place, at any rate, are also perceptible. Therefore, there is no unlimited body outside the heaven; nor yet is there one that is up to a certain limit. Therefore, there is no body at all outside the heaven. For if it is intelligible, it will be in a place; for outside and inside signify place. So it will be perceptible. But nothing perceptible is not in a place.

It is also possible to attack the issue in a more logico-linguistic way as follows. For the unlimited, when uniform, cannot move in a circle; for there is no center of the unlimited, while what moves in a circle moves around the center. But then neither can the unlimited spatially move in a straight line; for there would need to be another just as large (that is, unlimited) place that it will spatially move toward in accord with nature, and a distinct one, just as large, that it will move toward contrary to nature.

Further, whether it has its rectilinear movement by nature or by force, either way there will need to be an unlimited moving strength; for the unlimited strength is that of the unlimited and the strength of the unlimited is unlimited. So the mover will be also unlimited (there is an argument in the discussions concerning movement[32] that nothing limited has unlimited capacity and nothing unlimited has limited capacity). If, then, what can be moved in accord with nature can also be moved contrary to nature, there will be two unlimited things, the one that is a mover in this way and the one that is a moved.

Further, what is the mover of the unlimited? If it moves itself, it will be animate. But how is it possible for there to be an unlimited animal? But if the mover

32. *Ph*. 266^{a}27–^{b}27.

is something else, there will be two unlimited things, the mover and the moved, differing in shape and capacity.

If the universe is not continuous, but rather, as Leucippus and Democritus say, is divided into particles by the void, it is necessary for there to be one [sort of] movement for all things. For the particles are determined by their shapes, but, they say, their nature is a single one, as if each one were a separate piece of gold. Among these, as we say, it is necessary for there to be the same [sort of] movement; for where a single clod of earth spatially moves to, the totality of earth does as well, and both the totality of fire and a single spark spatially move to the same place. So none of these bodies will be unconditionally light if all have heaviness, while if all have lightness, none will be heavy. Further, whether they have heaviness or lightness, there will be some extremity or some center of the universe. But this is impossible if it is unlimited.

In general, where there is neither center nor extremity, and neither up nor down, there will be no place for the spatial movement of bodies. And if there is not this, there will not be movement; for it is necessary for things to move either in accord with nature or contrary to nature, and these are determined by their proper places, and by those of the others.

Further, if there is a place where a thing remains at rest or to which it spatially moves contrary to nature, it is necessary for there to be something else for which this place is in accord with nature (one may be persuaded of this on the basis of induction). It is necessary, then, that not everything have heaviness (or lightness), but rather for some to have it, and others not to have it.

That the body of the universe is not unlimited, therefore, is evident from these considerations.

1.8
There Cannot Be More Than One Heaven (1)

Let us now say why there cannot be several heavens either, for we said[33] that this must be investigated, in case someone thinks that it has not been proved universally about all bodies that it is impossible for any of them at all to exist outside the cosmos, but that the argument applies only to those with no definite position.

For all things both remain at rest and move both in accord with nature and by force, and, where they remain at rest not by force, they also spatially move to in accord with nature, and where they spatially move to [in accord with nature], they also remain at rest in [not by force]; on the other hand, where they remain at rest by force, they also spatially move to by force, and where they spatially move to by force, they also remain at rest in by force. Further, if this spatial movement is by force, its contrary is in accord with nature. If, then, earth will spatially move by force from

33. 274ᵃ24–28.

there to the center here, it will spatially move in accord with nature from here to there; and if earth from there remains at rest here not by force, it will spatially move toward here in accord with nature too. For the spatial movement that is in accord with nature is a single one.

Further, it is necessary for all the cosmoses, being admittedly similar in nature, to be composed of the same bodies. But then it is necessary for each body to have the same capacity—I mean, for example, fire and earth and the ones intermediate between them;[34] for if these are homonyms and are not said of things there in accord with the same form as of those among us, then the universe too would be said to be a cosmos homonymously. It is clear, therefore, that one of them must spatially move naturally away from the center, while another does so toward the center, if indeed all fire is the same in form as [other] fire (and also each of the others), just as the parts of fire in this cosmos are the same in form.

That this is of necessity so is evident from our hypotheses about movements; for the movements are limited, and each of the elements is said to be what it is with reference to one of the movements. So if indeed movements are in fact the same, it is necessary for the elements too to be everywhere the same.

Therefore, the parts of earth in another cosmos will be naturally such as to spatially move toward the center of this one, and fire there toward the extremity of this one. But this is impossible; for if this happens, it is necessary for earth in its own cosmos to spatially move upward, and fire toward the center. Similarly, the earth here will move in accord with nature away from the center in moving toward the center there, because of the way the cosmoses are positioned in relation to each other. For either we must not posit that the simple bodies have the same nature in the several heavens, or in saying that they do, it is necessary to make a unique center and a unique extremity. But if this is so, there cannot be more than one cosmos.

But to think that the nature of the simple bodies is then different the more or less distant they are from their proper places is unreasonable; for what difference will it make to say that they are this distant or that distant? They will differ in proportion to their increase in distance, but their form will remain the same.

Moreover, it is necessary for the simple bodies to have some movement; for that they do move is evident. Are we to say, then, that all their movements are by force, even contrary ones? But what does not naturally move at all cannot be moved by force. If, therefore, some movement in accord with nature belongs to them, it is necessary for the movement of particular ones that are the same in form to be toward a place that is one in number—for example, toward this particular center or this particular extremity. But if they are toward places that are the same in form, but many (because as particulars they are in fact many, but in form each is undifferentiated [from the others]), then there will not be such [a place] for one but not for another of the parts, but for all alike; for all are alike undifferentiated in form, although any one

34. I.e., air and water.

is distinct in number from any other. What I mean is this: if the parts here behave in a similar way both toward each other and toward the ones in another cosmos, then one taken from here will not behave differently toward the ones in another cosmos than toward those in its own, but in a similar way. So either it is necessary for these assumptions to be altered, or it is necessary for there to be a unique center and a unique extremity. But if this is so, then, by the same proofs and the same necessities, there must also be only one heaven and not several.

That there is a certain place that it is natural for earth to spatially move toward, and also one for fire, is clear from other [sorts of change]. For, in general, what moves changes from something to something, and these—the from which and the to which—differ in form. And all change is limited—for example, what becomes healthy changes from sickness to health, and what increases changes from smallness to largeness. So too for what spatially moves; for it too comes to be somewhere from somewhere. Therefore, what it naturally moves from and to must differ in form, just as what becomes healthy [does not change to] some random point, nor to whichever one the mover wishes.

Therefore, fire—and earth too—spatially moves not without limit but toward opposite points. But with respect to place up is opposed to down, so that these will be the limits of spatial movement. (Since even spatial movement in a circle has in a way opposite points, the end-points of its diameter, though to the whole movement nothing is contrary, so even for these the movement is in a certain way toward opposite and limited points.) Therefore, it is necessary for it to have some end and not spatially move without limit.

A proof of there being no spatial movement without limit is that earth, the closer it gets to the center the faster it spatially moves, while fire does so the closer it gets to the upper place. But if the spatial movement were without limit, its speed would be unlimited too, and if the speed were, so too would be the heaviness and the lightness involved; for just as[35] a thing that is lower than another is faster, another is faster because of its heaviness, so if the increase in heaviness were unlimited, the increase in speed would be unlimited as well.

277b1 But then neither could they be moved upward and downward by something else, nor by force or squeezing out, as some people say.[36] For then more fire would move more slowly upward and more earth more slowly downward. As things stand, however, the contrary always happens: more fire and more earth spatially move faster to their own place. Nor would it spatially move faster toward the end if it were by force and squeezing out; for everything spatially moves more slowly the further it gets from what did the forcing, and what it spatially moves from by force, it spatially moves to not by force. So by getting a theoretical grasp on these points it is possible to get adequately persuaded of what is being said.

35. Rejecting the addition of εἰ.
36. *DA* 404a1–16.

Further, [that there is a unique heaven] might also be proved by means of the arguments from primary philosophy, and from movement in a circle, which is necessarily eternal both here and in other cosmoses as well.[37]

It should also be clear to those who investigate in the following way that it is necessary for there to be a unique heaven. For since there are three corporeal elements, the places of the elements will also be three, one around the center for the body that sinks, another for the body that spatially moves in a circle, which is the extremity, and a third intermediate between them for the middle body. For it is necessary for what rises above to be in this one. For if it is not in this one, it will be outside. But it is impossible for it to be outside. For one is without heaviness, the other has heaviness, and the lower place is that of the body that has heaviness (if indeed the place of what is heavy is toward the center). Moreover, it could not be so, contrary to nature; for then it will be in accord with nature for another one; but there is, as we saw, no other one. Therefore, it is necessary for it to be in the intermediate place. What the differences of this place are, we will say later.[38]

Concerning the bodily elements, then, what sort they are and how many, and what the place of each is, and further, in general, how many in number the places are, is clear to us from what has been said.

1.9
There Cannot Be More Than One Heaven (2)

That not only is the heaven[39] unique, but that there cannot come to be more, and further, that it is eternal, being incapable of coming to be and of passing away, we should now state, first of all going through the puzzles about this.

For it might seem to those who investigate in the following way that there cannot be one, unique heaven; for in everything that is constituted and has come to be by nature or by craft, the shape [or form] taken intrinsically and the shape mixed together with the matter are distinct. For example, the form of the sphere and the gold or bronze sphere are distinct; and, again, the shape of the circle and a brazen or wooden circle are distinct; for in stating the essence for sphere or for circle, we do not mention bronze or gold in the account, on the supposition that these are not [parts] of its substance; while if we are speaking of the brazen or golden one, we do mention it, and we do so even when we cannot understand or grasp any other, beyond the particular one. For sometimes nothing prevents this from happening—for example, if only one circle were grasped; for the being for circle will be no less distinct from the being for this circle, and the one is the form, while the other is the form in the matter, that is, one of the particulars.

37. *Met.* 12.6–10, especially 1074ᵃ31–38.
38. 4.4.
39. Reading ἐστὶν οὐρανός.

Since, then, the heaven is perceptible, it will be one of the particulars; for everything perceptible is in matter. But if it is one of the particulars, the being for this heaven and the being for heaven unconditionally will be distinct. Therefore, this heaven and heaven unconditionally will be distinct, and the latter as being form and shape, the former as being mixed with matter. But of what there is a certain shape or form of, there either is or can come to be many particular instances. For if there are Forms, as some say,[40] it is necessary for this to result—and no less so if nothing of this sort is separable; for we see in all cases in which the substance [= essence] is in matter that things of the same form are several, indeed unlimited in number. So either there are or can be several heavens.

On the basis of these considerations, then, one might suppose either that there are or that there can be several heavens. We must go back, however, and investigate which of these is correctly stated and which not correctly.

That the account of the shape [or form] without the matter and of the one in the matter are distinct is correctly stated, and let it be true. But nonetheless there is no necessity, because of this, for there to be several cosmoses, nor even that several can come to be, if indeed this one is composed of the totality of matter, as in fact it is.

What is being said will perhaps be clearer put in the following way. For if aquilinity is curvature in a nose, or in other words, in flesh, and if flesh is matter for aquilinity, then if of the totality of flesh one [parcel of] flesh were to come to be composed, and the aquiline belonged to it, nothing else either would or could be aquiline. Similarly, if fleshes and bones are matter for what is human, if of the totality of flesh and of all the bones a human were to come to be composed in a way incapable of dissolution, it would be impossible for another human being to be. And similarly in other cases; for in general, nothing whose substance is in some underlying matter can come to be without there being some matter.

The heaven is certainly one of the particulars and one of the things composed of matter. But if it is composed not of a part of matter but of the totality of it, the being for the heaven itself and for this heaven are distinct, yet it is not the case either that there is another one or even that several could come to be, because this one includes the totality of the matter. It remains, therefore, to prove this: that the heaven is composed of the totality of natural and perceptible body.

Let us first state what we say it is to be heaven and in how many ways, in order that what we are inquiring about will become clearer to us. In one way, then, we say that the substance belonging to the outermost revolution of the universe is heaven, or the natural body that is on the outermost circumference of the universe; for more than anything else it is the last upper region that we usually call "heaven," the one in which we say that everything divine also has its seat. In another way, it is the body that is continuous with the outermost circumference of the universe, in which we find the moon, the sun, and some of the stars; for we say that these bodies too

40. I.e., Plato and his followers.

are in the heaven. Further, we say that the body that is encompassed by the outermost circumference is heaven; for we are accustomed to say that the whole and the universe is heaven. Something is said to be heaven, then, in three ways. The whole encompassed by the outermost circumference is of necessity composed of the totality of natural and perceptible body, because there neither is nor can be any body outside the heaven.

For if there is a natural body outside the outermost circumference, it is necessary for it to be either one of the simple bodies or one of the composite ones, and for it to be there either in accord with nature or contrary to nature. But it could not be one of the simple ones. For it has been proved[41] that the one that spatially moves in a circle cannot change its own place. But neither can it then be the one that moves from the center nor the one that sinks. For they could not be there in accord with nature (for other places are proper for them), while if indeed they are there contrary to nature, the place outside will be natural for some other body; for what is contrary to nature for it is of necessity in accord with nature for something else. But there is, we saw, no other body beyond these. Therefore, it is not possible for any of the simple bodies to be outside the heaven. But if none of the simple ones can be, neither can any of the mixed ones; for where the mixed one is, it is necessary for the simple ones to be as well.

Moreover, neither can a body come to be there; for it will do so either in accord with nature or contrary to nature, and it will be either simple or mixed, so that, again, the same argument will apply; for it makes no difference to investigate if it is, or if it can come to be.

It is evident, therefore, from what has been said that no corporeal mass either is or is allowed to come to be outside [the heaven]. Therefore, the total cosmos is composed of the totality of its proper matter; for its matter is natural and perceptible body. So neither are there now several heavens, nor have there been, nor can there come to be several ones. On the contrary, this heaven is one, unique, and complete.

At the same time, it is clear that there is neither place, nor void, nor time outside the heaven. For in every place body can exist; and void, they say, is that in which body does not exist, but in which it can; and time is a number of movement, and there is no movement without natural body. But it has been proved that outside the heaven there neither is nor can be body. Therefore, it is evident that there is neither place nor void, nor time outside it.

That is why things that are there are naturally such as not to be in place, nor does time age them, nor is there any change for any of the things that are stationed above the outermost spatial movement; instead, unalterable and unaffectable, having the best and most self-sufficient life, they are attaining their end throughout all eternity (*aiôn*). (For in fact this name, *aiôn*, was given utterance by the ancients in a divinely inspired way. For the end that encompasses the time of a given thing's life, outside

41. 1.2–3.

of which nothing exists in accord with nature, is called the *aiôn* ("lifetime") of it. And by the same argument, the end of the entire heaven too, that is, the end that encompasses all of time and the unlimited, is *aiôn*, immortal and divine, deriving its name from its always being (*aiei einai*).) From it too the being and life for other things derive, for some in a more exact way, for others in a more indistinct one.

And in fact, just as in the philosophical studies in circulation concerning things divine, it is often brought to light in the arguments that whatever is divine, whatever is primary and highest, is necessarily unchangeable. The fact that this is so attests to what has been said. For neither is there anything else greater that will move it (for then that thing would be more divine), nor has it any defect, nor does it lack any of the noble things proper to it. That it is moved with an unceasing movement is also reasonable; for everything ceases moving when it arrives at its proper place, but, in the case of the body that moves in a circle, the place it starts from and at which it ends are the same.

1.10
The Cosmos Is Incapable of Coming to Be or Passing Away (1)

Having determined these matters, let us say next whether [the cosmos] is incapable of coming to be or capable of coming to be, and incapable of passing away or capable of passing away, having first gone through the suppositions of others; for in the case of contrary ones the demonstrations belonging to one lot are puzzles for the contrary lot. At the same time, what we are about to say will also be more convincing to people who have previously heard the pleas of the arguments disputing them. For then we will less seem to be securing a favorable judgment by default; for in fact those who are going to judge the truth adequately must be arbitrators rather than legal opponents.

Everyone says, then, that it has come to be, but some say that having come to be it is eternal, while others say that it is capable of passing away, just like any of the other things that are put together; still others say that it is alternately sometimes in the one state and other times in the other (passing away), and it continues being like this always, as Empedocles of Acragas and Heraclitus of Ephesus say.

To state that it has come to be but is nonetheless eternal is to state impossible things. For it is reasonable that one must posit only those things that we see to hold in many or in all cases, and in this one it is the contrary that happens; for it is evident that everything that comes to be also passes away.

Further, what has no starting-point of its present state, but rather was incapable of being otherwise throughout the entirety of its previous lifetime, is also incapable of changing; for there will be some cause [of its change], and if this had obtained previously, what is incapable of being otherwise would have been capable of being otherwise.

If the cosmos were composed of things that were previously otherwise, if they were always this way and incapable of being otherwise, it would not have come to be, while, if it did come to be, it is clearly also necessary for these things to be capable of being otherwise and not always the same. So what has been composed will be dissolved and, if dissolved, was previously composed. And this either has taken place, or is capable of having taken place, an unlimited number of times. But if this is so, it will not be incapable of passing away, whether it was otherwise at some time or capable of being otherwise.

The aid with which some of those who say that the cosmos came to be but is incapable of passing away attempt to support their case is not a true one; for they say that they speak about coming to be in a similar way to those who draw geometrical diagrams, not as of something coming to be at some time, but rather for the sake of teaching, on the supposition that it makes things easier to come to know, just as the diagram does for those who see it coming to be. But the two cases, as we say, are not **$280^{a}1$** the same; for in the production of geometrical diagrams, if everything is assumed to exist at the same time, what results is the same, while in the demonstrations these people give it is not the same, but rather something impossible; for the earlier and later assumptions are contrary ones; for they say that ordered things came from disordered ones, yet things cannot be ordered and disordered at the same time. Instead, it is necessary for there to be a process of coming to be separating the two, as well as a period of time. In geometrical diagrams, by contrast, nothing is separated by time. That it is, then, impossible for it [the cosmos] to be at once eternal and have come to be is evident.

Having it be alternately composition and dissolution is doing nothing other than establishing it as eternal but changing its shape, just as if one thought that a man coming to be from a boy or a boy from a man is at one time passing away and at another is in being; for it is clear that, whenever the elements are coming together with each other, it is not any random order and composition that comes to be, but rather the same one, especially according to those who state this account, since they assign to each of the two dispositions [of the elements] a contrary cause.[42] So if the whole body, being continuous, is at one time disposed and ordered in this way and at another time in that way, and the composition of the whole is a cosmos, that is, a heaven, then the cosmos would not come to be and pass away, but its dispositions would.

And it is impossible that, having come to be, it passed away as a whole, without making a return, since it is one; for before it came to be, the composition before it always existed, and, not having come to be,[43] cannot (we say) change. If there are

42. As Empedocles makes love the cause of composition and its contrary, strife, the cause of dissolution.

43. I.e., up to the moment of its supposed beginning (279^{b}21–24).

an unlimited number [of cosmoses], however, this is more possible. Nonetheless, whether even this is impossible or possible will be clear from later considerations.[44]

Indeed, there are some people to whom it seems possible both for something that is incapable of coming to be to pass away, and for something that has come to be to remain incapable of passing away, as in the *Timaeus*;[45] for there he says that while the heaven came to be, nonetheless it will always be for the remainder of time.

In relation to these [thinkers] we have spoken about the heaven only in natural scientific terms, but when we have investigated everything in universal ones, things will be clear about this issue too.

1.11
Ways in Which Things Are Incapable of Coming to Be or Passing Away

But first of all we must distinguish the ways in which we say things are incapable of coming to be, capable of coming to be, capable of passing away, and incapable of passing away; for these are said of things in many ways, and even if this makes no difference to the argument, thought will be indefinite if one uses what is divided in many ways as undivided; for it is unclear with reference to which nature what is said applies to it.

Something is said in one way to be incapable of coming to be if it is now but previously was not, without any coming to be or change, as is the case, some people say,[46] with being in contact and being in movement; for there is not, they say, a coming to be when something is in contact [with something else] or in movement. In another way, if something can come to be, or can have come to be, but is not; for this too did not come to be, because it can come to be [but did not do so]. In another way, something is incapable of coming to be if it is wholly incapable of coming to be, so that it is at one time and is not at another. (For something is said to be incapable [of this] in two ways: because of its not being true that it could come to be; or because of its not doing so easily, quickly, or well.)

It is the same way too with capable of coming to be. Something is capable of coming to be in one way if it previously is not but later is: whether having come to be or without coming to be, it is not at one time, but is at another. In another, if it is capable [of coming to be], defining "being capable" either in terms of its being true that it can, or in terms of its doing so easily. In another, if there is a coming to be of it from not being to being, whether—because of coming to be—it already is, or is not yet, but can be.

And capable of passing away and incapable of passing away are [said of things] in like manner; for whether something that previously is, later is not, or admits of not

44. Reference unclear.
45. Perhaps 41a–b.
46. Zeno, the Atomists, and the Platonists have all been suggested as likely candidates.

being, we say it is capable of passing away, whether it is passing away and changing at some time or not. Sometimes too we say that of what (because of passing away) admits of not being that it is capable of passing away, and in yet another way, we say it of what easily passes away—what is prone to passing away, as one might say.

And the same account applies to what is incapable of passing away. For it is either what, without passing away, is at one time but is not at another—for example, contacts, because, without passing away, these are previously but later are not. Or it is what is, but is capable of not being, or what will not be at some time but now is; for you and a contact are now; nonetheless, both are capable of passing away, because there will be a time at which it is not true to say that you are, or that these things are making contact. But most strictly speaking [what is incapable of passing away] is what now is and is incapable of passing away in such a way that it now is but later is not or cannot be. Or else it is what has not yet passed away, but cannot be later on. And something is also said to be incapable of passing away when it does not pass away easily.

If these things are indeed so, in what ways we say things are capable and incapable must be investigated; for we say that something is incapable of passing away most strictly speaking because it is not capable of passing away, that is, cannot at one time be and at another not be. And what is incapable of coming to be is also said to be incapable, that is, not capable of coming to be in such a way that previously it is not and later it is—for example, [as we say] that the diameter is not capable of being commensurable.

But if indeed something is capable of moving, or of lifting a weight, we always say so with reference to the greatest one—for example, of lifting one hundred talents or walking one hundred stades (and yet it is also capable of doing the parts within it, if indeed it is capable of doing the maximum), as the capacity must be defined in relation to the end, that is, the maximum. It is necessary, then, for what is capable of the maximum to be capable of what is within it—for example, if one is capable of lifting one hundred talents, one is also capable of lifting two, and if capable of walking one hundred stades, one is also capable of walking two. Indeed, the capacity is a capacity for the maximum. And if something is incapable of doing so-and-so much, speaking with reference to a maximum, it is also incapable of greater ones—for example, if a person is not capable of walking one thousand stades, it is clear that he is also incapable of walking one thousand and one.

None of this should trouble us; for let what is capable in the strict sense be defined by the end in the sense of the maximum. For perhaps someone might object that what has been said is not necessarily so; for a person who sees a stade will not also see the magnitudes within it; on the contrary, it is rather the case that a person who is capable of seeing a point or of hearing a small sound will also perceive greater ones. But this makes no difference to the argument; for let the maximum be defined either with respect to the capacity or with respect to the thing [it is a capacity for]. For what

is being said is clear; for while the sight of the smallest thing is the maximal sight, the speed [covering] the greater distance is the maximal speed.

1.12
The Cosmos Is Incapable of Coming to Be or Passing Away (2)

Having made these determinations, what comes next must be discussed. If, then, some things are capable of being and of not being, it is necessary that there be some greatest time determined both for their being and for their not being; I mean, during which the thing at issue is capable of being and capable of not being, with respect to any category—for example, [being or not being] human, white, three cubits long, or anything else of this sort. For if there will not be a certain quantity [of time], but always a longer one than any proposed and none than which it is shorter, the thing will be capable of being for an unlimited time, and of not being for another unlimited time—but this is impossible.

Let our starting-point be the following: Impossible and false do not signify the same thing. There is an impossible and possible, a false and a true, that are based on a hypothesis (I mean, for example, it is impossible for a triangle to contain two right angles and it is impossible for the diameter to be commensurable, if these things hold). But there are also things that are possible and impossible, false and true, unconditionally. It is not the same thing, then, for something to be unconditionally false and to be unconditionally impossible. For to say, when you are not standing, that you are standing is false, but not impossible. Similarly, to say that a person playing the lyre, but not singing, is singing is false, but not impossible. But for someone to be standing and sitting at the same time, and for the diagonal to be commensurable, it is not only false, but also impossible. It is not the same thing, then, to assume something false and something impossible. And the impossible results from the impossible.

A person does of course at the same time have the capacity for sitting and for standing, because when he has the one, he also has the other—not so as to be sitting and standing at the same time, though, but rather at distinct times. But if something has a capacity for several things for an unlimited time, "at distinct times" does not apply, but rather "at the same time."

So if for an unlimited time something is capable of passing away, it would have the capacity for not being. If, then, it has it for an unlimited time, let what it is capable of doing be realized. At the same time, therefore, it will actively be and not be at the same time. A falsehood would result, then, because a falsehood was assumed. But if what was assumed was not impossible, the result would not actually be impossible. Therefore, everything that always is, is unconditionally incapable of passing away.

Similarly, it is also incapable of coming to be; for if it is capable of coming to be, it will be capable of not being at some time—for while a thing capable of passing away is one that is previously, but now is not or cannot be at some later time, a one capable of

coming to be is one that can previously not be. But there is no time in which what always is, is capable of not being, whether for an unlimited or for a limited one; for it is also capable of being in a limited time, if indeed it is in fact capable of being in an unlimited one. Therefore, one and the same thing cannot be capable of being always and of not being always. Moreover, the negation is not possible either, I mean, not always being. Therefore, it is also impossible for something to always be and to be capable of passing away. Neither, similarly, is it capable of coming to be; for of two terms, if it is impossible for the posterior one to hold [of something] without the prior one, and if it is impossible for the prior one to hold, it is also impossible for the posterior one to hold. So if what always is cannot at some time not be, it is also incapable of coming to be.

And since the negation of what is always capable of being is what is not always capable of being, while its contrary is what is always capable of not being, the negation of which is what is not always capable of not being, it is necessary for the negations of both to belong to the same thing, and that what is capable of being and of not being be intermediate between what always is and what always is not; for the negation of each will belong to it at some time, if not always. So if what not always is not will be at some time and not be at some time, clearly what is capable of not always being but is at some time will as well, so that it too will not be. Therefore, the same thing will be capable of being and of not being, and it is intermediate between the two.

The universal argument is this: Let A and B be not capable of belonging to the same thing, and let A or C and B or D belong to everything [Fig. 8].

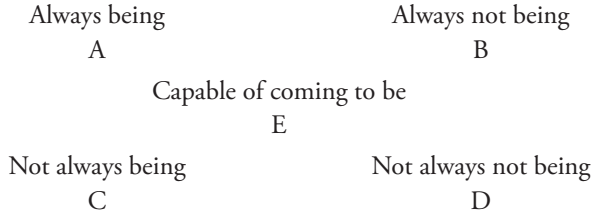

Fig. 8

It is necessary then that C and D belong to everything that is neither A nor B. Then let E be intermediate between A and B (for what is neither of two contraries is intermediate). It is necessary, then, for both C and D to belong to it. For A or C belongs to everything, so that one of them will also belong to E. Since, then, it is impossible that A belong to it, C will belong to it. The same argument also applies to D.

Neither what always is, then, nor what always is not is either capable of coming to be or capable of passing away. But it is clear too that if something is capable of coming to be or capable of passing away, it is not eternal. For it will at the same time be capable of always being and capable of not always being; but that this is impossible was proved previously.[47]

47. 281ᵇ20–25.

If, then, something is incapable of coming to be, but is, is it necessary for it to be eternal, and likewise if something is incapable of passing away, but is? (I mean incapable of coming to be and incapable of passing away strictly speaking: by "incapable of coming to be" I mean what is now and previously it was not true to say that it is not; by "incapable of passing away" I mean what is now and it will not be true to say later that it is not.)

Or, rather, if these things follow along with each other, and what is incapable of coming to be is incapable of passing away and what is incapable of passing away is incapable of coming to be, then it is necessary for eternality to follow along with each of them, and in either case, whether something is incapable of coming to be or incapable of passing away, it is eternal. This is also clear from their definition; for necessarily, in fact, if something is capable of passing away, it is capable of coming to be. For it is either incapable of coming to be or capable of coming to be. But if it is incapable of coming to be, it has been established[48] that it is incapable of passing away. And if it is capable of coming to be, then it is necessarily capable of passing away; for either it is capable of passing away or incapable of passing away. But if it is incapable of passing away, it has been established[49] that it is incapable of coming to be. If, on the other hand, incapable of passing away and incapable of coming to be do not follow along with each other, it is not necessary for either what is incapable of coming to be or what is incapable of passing away to be eternal.

But that it is necessary for them to follow along is evident from the following considerations. For capable of coming to be and capable of passing away follow along with each other. This too is clear from the previous [arguments]; for between what always is and what always is not there is an intermediate that follows along with neither of them, that is, what is capable of coming to be and capable of passing away. For it is capable of both being and of not being for a definite time (I mean of being for a quantity of time and of not being [for a quantity of time]).

If, therefore, something is capable of coming to be or capable of passing away, it is necessary for it to be intermediate. For let A be what always is, B what always is not, C what is capable of coming to be, and D what is capable of passing away [Fig. 9].

Always being A	Capable of coming to be C
Capable of passing away D	Always not being B

Fig. 9

It is necessary, then, for C to be intermediate between A and B. For there is no time in the direction of either limit in which either A was not or B was. But for what is

48. 281b25–33.
49. 281b33–282a1.

capable of coming to be, it is necessary to be either actively or potentially, and for A and B neither of them. Therefore, it [= C] will be, and again not be, for some definite quantity of time. And likewise too in the case of D. Therefore, each of the two is capable of coming to be and capable of passing away. Therefore, capable of coming to be and capable of passing away follow along with each other.

Let E be incapable of coming to be, F be capable of coming to be, G be incapable of passing away, and H be capable of passing away. As for F and H, it has been proved[50] that they follow along with each other. But whenever things are established to be related as these are, such that F and H follow along with each other, and E and F never belong to the same thing, but one or the other belongs to everything, and likewise for G and H, then it is also necessary that E and G follow along with each other. For let E not follow along with G. Therefore, F will follow along with G; for E or F belongs to everything. But then H also belongs to whatever F belongs to. Therefore, H will follow along with G. But it has been established that this is impossible. The same argument proves too that G follows along with E. **283^{a}1**

Moreover, the same relation holds between what is incapable of coming to be, E, and what is capable of coming to be, F, as between the incapable of passing away, G, and what is capable of passing away, H [Fig. 10].

Incapable of coming to be	Capable of coming to be
E	CF
Incapable of passing away	Capable of passing away
G	H

Fig. 10

To say that nothing prevents something that comes to be from being incapable of passing away, and something incapable of coming to be from having passed away, if in the one case coming to be and in the other the passing away occurs only once, is to do away with one of the things that have been granted. For all things are capable either of affecting or of being affected, of being or of not being, for either an unlimited or for some definite quantity of time (and an unlimited one [simply] because of this, because the unlimited is in a way definite, being what nothing is greater than). What is unlimited in some way, then, is neither unlimited nor definite.

Further, why at this point rather [than any other] did what previously always was pass away, or what previously always was not come to be? For if there was no reason [in favor of a certain point], and the points are unlimited [in number], it is clear that for an unlimited time something was capable of coming to be and capable of passing away. Therefore, it was capable of not being for an unlimited time. Therefore,[51] it will at the same time have a capacity for not being and for being—beforehand, if

50. 281^{b}20–25.
51. Reading ἄρ'.

it is capable of passing away, afterward, if it is capable of coming to be. So if we suppose the things it is capable of doing to be realized, contraries will belong to it at the same time.

Further, these things will belong to it alike at every point in time, so that for an unlimited time it will have a capacity for not being and for being; but it has been proved[52] that this is impossible.

Further, if the capacity belongs to it prior to its activation, it will belong to it for the entirety of time, even when it had not come to be and was not but was capable of coming to be. At the same time, then, it was not and had a capacity for being, both for being then and later on—therefore for an unlimited time.

It is also evident in another way that it is impossible for what is capable of passing away not to pass away at some time. For it will always be at the same time both capable of passing away and incapable of passing away in actuality. So at the same time it will be capable of always being and of not always being. Therefore, what is capable of passing away passes away at some time. And if it is capable of coming to be, it has come to be [at some time]; for it was capable of having come to be, and therefore of not always being.

It can also be seen in the following way that it is impossible either for what has come to be at some time to remain incapable of passing away, or for what is incapable of coming to be and previously always was to pass away. For nothing can be by chance either incapable of passing away or incapable of coming to be. For what is by chance or by luck is beyond what always or for the most part either is or comes to be. But what is for an unlimited time, whether unconditionally or from a certain point, exists either always or for the most part.

Therefore, it is necessarily by nature that things of this sort are at some times and not at others. And in things of this sort the same capacity is for what is contradictory, and the matter is the cause of their being and not being. So it is necessary for opposites to belong actively too at the same time.[53]

Moreover, it is not true to say now that something is last year, or last year that something is now. Therefore, it is impossible for what is not at some time to be eternal at a later one; for later it will also have the capacity for not being—except not one for not-being-at-the-time-when-it-is (for then actively being will belong to it), but for not being last year or in time past. Let, then, what it is a capacity for belong to it actively. It will, therefore, be true to say of it now that it is not last year. But this is impossible; for there is no capacity for having come to be, but [only] for being now or being in the future. Likewise, if previously it is eternal and later will not be; for it will have a capacity for what actively is not. So if we suppose what it is capable of to be realized, it will be true to say now that it is last year and, in general, in time past.

52. 281b20–25.
53. Reading καὶ ἅμα.

And if we investigate in a natural scientific way, and not in universal terms, it will be impossible either for something that previously eternally is to pass away later, or for what previously is not to be eternal later on. For things that are capable of coming to be and capable of passing away are all alterable as well. But they are altered by their contraries, and the things from which natural beings are composed are also the very same ones by which they are caused to pass away.

BOOK 2

2.1
Corroboration from Ancient Views

It is possible to obtain the conviction that the entire heaven has neither come to be nor is it possible for it to pass away, as some people say it is, but is one and eternal, having neither starting-point nor end-point of its entire lifetime but encompassing the infinite time within itself, on the basis of what has been said, and by means of the doctrine of those who speak otherwise by having it come to be; for if it is possible for things to be as we say, but not possible for them to be in the way described by those who say it comes to be, this should add great weight to the conviction about its being immortal and eternal. **284^{a}1**

That is why it is well to convince oneself that the ancient accounts, especially those of our forefathers, are true, that there is something immortal and divine among the things that have movement, having movement of such a sort that there is no limit to it, but rather it is the limit of the others; for the limit belongs to what encompasses, and this movement, being complete, encompasses the incomplete ones that have a limit and a cessation, while itself has neither a start nor an end, but rather is unceasing throughout unlimited time, and is the cause of the start of certain among the incomplete ones, and receives the cessation of others.

The ancients assigned the heaven, that is, the upper place, to the gods on the supposition that it alone is immortal. And the present account testifies to its being incapable of passing away and incapable of coming to be, and further, to its being unaffectable by all mortal difficulty, and, in addition to these, it is unlabored, because it needs no additional necessary force which restrains it, preventing it from spatially moving in another way that is natural to it; for everything of that sort is laborious, the more so the more eternal it is, and without a share of the best disposition.

That is why one must not suppose it to be in accord with the myth of the ancients,[54] who say that the heaven has the additional need of some Atlas for its preservation; for it seems that the people who composed this account had the same supposition as the

54. E.g., Hesiod, *Theogony* 517.

later ones; for on the supposition that all bodies have weight and are earthen, they supported the heaven in mythical fashion with an animate necessity.

One must not, then, suppose it to be this way, nor that, because of its whirling's having a spatial movement that is faster than its own balance-weight, the heaven has been preserved [from falling to the earth] for all this time, as Empedocles says.[55]

But neither is it reasonable that the heaven remains eternal because a soul necessitates it; for it is not possible for this sort of life to be painless and blessedly happy for a soul; for it necessarily, with respect to its movement,[56] involves force—if indeed it moves the primary body in another way than with its natural spatial movement, and moves it continuously—and is unleisured and deprived of all thought-involving ease, if indeed it does not possess, as does the soul of mortal animals, any of the rest that is the relaxation of the body that occurs in sleep. Instead, it is necessary that a fate of some Ixion, eternal and indefatigable, restrain it.

If, then, as we said, it is possible for the primary spatial movement to be the way we have stated, not only is it more refined to think this way about its eternity, but also this is the only way to provide harmonious accounts that are in agreement with the prophecy around and about the god. But let this be enough about these sorts of accounts for now.

2.2
Up and Down, Left and Right

Since there are some people who say that there is some right and left in the heaven, such as those called "Pythagoreans" (for this account is theirs), we must investigate whether this is the way they say it is, or rather in a distinct one, if indeed one must ascribe these starting-points to the body of the universe.

For first of all, if right and left do belong [to the heaven], one must suppose that prior starting-points belong to it in a prior way. These things have been determined in our studies on the movement of animals, because they properly belong to the nature of animals;[57] for manifestly in some animals it is evident that all parts of this sort belong (I mean, for example, right and left), in others [only] some, while in plants only up and down belong. If, however, one must ascribe something of this sort to the heaven as well, it is reasonable that the first one, as we said, that belongs in animals belongs in it too; for there are three [pairs], each of which is a starting-point of a sort. The three I mean are up and down, front and its opposite, and right and left; for it is reasonable that all these dimensions belong to complete bodies. Up is a starting-point of length, right of breadth, and front of depth. Further, [they are starting-points] in another way, in accord with movements; for I mean by "starting-points" these things

55. B35 DK.
56. Reading κατὰ τὴν κίνησιν.
57. In particular, *IA* 4–5.

from which the movements first start for the things that have them. Growth starts from the up, movement with respect to place from things right, and perception from the front; for by "front" I mean what perceptions are directed toward.

That is why one must not look for up and down, right and left, and front and back in every body, but only in those that, being animate, have a starting-point of movement within them; for in inanimate ones we do not see the starting-point from which the movement derives; for some things do not move at all, while others, though they do move, do not do so in every direction alike—for example, fire moves upward only and earth toward the center. But in things of this sort we speak of up and down and **285^{a}1** right and left with reference to ourselves; for we speak of them either with reference to our own right, as prophets do, or with reference to what is similar to our right, as with the sides of a statue, or of what has its position in the contrary way, speaking of right with reference to our left, and left with reference to our right, and of back with reference to our front. In these things themselves, on the other hand, we do not see any differences; for if they are turned around, we call their contraries "right," "left," "up," "down," "front," and "back."

That is why one might wonder at the Pythagoreans because they said that only two of these, right and left, are starting-points, but omitted the four [remaining] starting-points, which are no less controlling; for in all animals up has no less a difference in relation to down, and front in relation to back, than things right have in relation to things left. For some of these differ in capacity only, others in their shapes as well; and the up and down is present in all animate things, animals and plants alike, but right and left is not present in plants.

Further, since length is prior to breadth, if up is a starting-point of length, right of breadth, and the starting-point of what is prior is prior, up would be prior to right in coming to be, since things are said to be prior in many ways.

In addition to these, if up is where movement derives from, right what movement starts from, front what it is directed toward, in this way too up will have a certain capacity in relation to the other forms [of dimensionality].

It is just, then, to criticize the Pythagoreans because they omitted the most controlling starting-points, and because they thought that the starting-points belong alike in all things.

Since we have determined previously[58] that capacities of this sort belong in things that have a starting-point of movement, and the heaven is animate,[59] that is, has a starting-point of movement, it is clear that it also has both up and down and right and left.

For there is no need to be puzzled, because the shape of the universe is spherical, as to how there can be a right and a left of it when all its parts are similar and all the time moving. Instead, we should understand that it is as if it were a thing in which there **285^{b}1**

58. *IA* 4–5.
59. 292^{a}18–21.

is a difference between right and left, even in their shapes, around which someone has afterward placed a sphere; for it will then have the capacity corresponding to the difference, but would seem not to because of the uniformity of its shape. It is the same way with the starting-point of movement; for even if it never began moving, nonetheless it is necessary for it to have a starting-point from which it would have begun if it had begun moving, and, if it were to come to a stop, from which it would start moving again.

I mean by the "length" of it the interval between its poles, and of the poles, one is up and the other down; for only in these hemispheres do we see a difference, because of their poles not moving. At the same time, we are also accustomed to saying that the sides in the cosmos[60] are not up and down, but rather what is beside the poles, on the supposition that length is this thing [we said it is]; for what is to the side is what is beside the up or the down.

Among the poles, however, the one that appears above us is down, the one invisible to us is up. For we say that the right of a given thing is where the starting-point of its movement with respect to place derives from. And in the case of the heaven the starting-point of its revolution is where the stars rise from, so that this would be right, and where they set would be left. If, then, it starts from the right and revolves to the right,[61] it is necessary for the non-apparent pole to be up; for if it is the apparent one, the movement will be to the left, which is precisely what we say it is not. Therefore, it is clear that the non-apparent pole is up, and the people who dwell there are in the upper hemisphere and near the right-side things, while we are in the lower one and near the left-side ones, which is contrary to what the Pythagoreans say; for they put us up and in the right [part] and put the people there [in the other hemisphere] down and in the left one. But the opposite turns out to be the case.

But with respect to the second revolution, that is, the revolution of the planets, we are in the upper and in the right [parts], while those others are in the lower and in the left ones; for the starting-point of movement is the reverse for the planets because their spatial movements are contrary, so that as a result we are near the starting-point, while they are near the end-point.

About things relating to the dimensions of the parts [of the cosmos] and to their definitions with respect to place, let these be the things that are said.

2.3
Why There Are Several Spatial Movements in the Heaven

Since movement in a circle is not contrary to movement in a circle, let us investigate why there are several spatial movements—even though we have to try to make our inquiry from far away—far away not in place, but much more in virtue of the fact

60. I.e., the regions of the cosmos lying outside the poles, or at an angle to the north-south axis.

61. I.e., counterclockwise.

that we have perception of altogether few of their [intrinsic] coincidental affections. Nonetheless, let us speak about the issue.

The cause of [there being several spatial movements] must be grasped from the following. Each thing of which there is a work is for the sake of the work.[62] The activity of a god is immortality, and this is eternal living. So it is necessary that eternal movement belongs to the god. And since the heaven is such (for it is a certain divine body), because of this it has a circular body, which by nature always moves in a circle.

Why, then, is the whole body of the cosmos not like this? Because it is necessary for some part of the body spatially moving in a circle to remain at rest, the part at the center. But no part of it can remain at rest either in general or at the center. For then in fact its movement in accord with nature would be toward the center; but by nature it moves in a circle; for [otherwise] its movement would not be eternal; for nothing contrary to nature is eternal.[63] But what is contrary to nature is posterior to what is in accord with nature, and, within coming to be, what is contrary to nature is a sort of departure from what is in accord with nature. It is necessary, therefore, for there to be earth; for it rests at the center. Let this be assumed for now; later this will be proved about it.[64]

But then if there is earth, it is necessary for there to be fire as well; for if one of two contraries is by nature, it is necessary for the other—if indeed it is a contrary and has some nature—to be by nature as well; for the matter of contraries is the same; the positive is prior to the privation (I mean, for example, that hot is prior to cold); and rest and heaviness are said of things in accord with a privation of lightness and movement. But then if indeed there is fire and earth, it is necessary for there also to be the bodies intermediate between them; for each element has a contrariety in relation to each. Let this too be assumed for now; later we must try to prove it.[65]

Since these elements exist, it is evident that it is necessary for there to be coming to be, because none of them can be eternal; for contraries are affected by, and affect, each other, and are destructive of each other. Further, it is not reasonable for something movable to be eternal, whose movement in accord with nature does not admit of being eternal. But of these there is [such] movement. That it is, therefore, necessary for there to be coming to be is clear from these considerations. **$286^{b}1$**

But if there is coming to be, it is also necessary for there to be another spatial movement, either one or many; for with respect to the spatial movement of the whole, the elements of the bodies necessarily relate to each other in the same way. We will speak more perspicuously about this in what follows.[66]

62. *Met.* $1050^{a}21–22$.
63. $269^{b}6–10$.
64. 2.14.
65. 4.4, *GC* 2.3–4.
66. The reference is probably to *GC* 2.10.

For now, though, this much is clear: due to what cause the circular bodies are many, namely, because it is necessary for there to be coming to be; and there is coming to be if indeed there is fire; and there is fire and the other elements if indeed there is earth; and there is earth because it is necessary for there to be something that always remains at rest if indeed it is necessary that there be something that is always in movement.

2.4
Why the Shape of the Heaven Must Be Spherical

It is necessary for the heaven to have a spherical shape; for this most properly belongs to its substance and is by nature primary.

Let us speak in universal terms about shapes, about what sort is primary, both among plane figures and among solids. Every plane figure, of course, is either rectilinear or curvilinear. And the rectilinear is encompassed by several lines, the curvilinear by one line. Since in each kind, the one is prior by nature to the many, and the simple to the compound, the circle would be the primary plane figure.

Further, if indeed the complete is that outside which no part of it can possibly be found, as it was previously defined, and it is always possible to add to the straight line, but never to that of the circle, it is evident that the one encompassing the circle will be complete. So if the complete is prior to the incomplete, because of this too the circle would be primary among the shapes.

Similarly, the sphere is primary among the solids; for it alone is encompassed by one surface, while rectilinear solids are encompassed by several; for as the circle stands among plane figures, so the sphere stands among solids.

Further, even those[67] who divide bodies into plane figures and generate them from plane figures are apparently witnesses to this; for the sphere is the only solid that they do not divide, because of its not having more than one surface; for the division into plane figures is not as someone cutting something into parts would divide the whole, but rather into things that are distinct in form.

That the sphere is primary among the solids, then, is clear. And it is also most reasonable for those[68] who assign [the shapes] a numerical order to do so by assigning [the number] one to the circle, two to the triangle (since it has [interior angles equal to] two right angles). But if one is assigned to the triangle, the circle will no longer be a shape.

Since the primary shape belongs to the primary body, and the primary body is the body in the outermost revolution, the body that spatially revolves in a circle will be spherical. So too, therefore, is the body continuous with it; for what is

67. E.g., Plato, *Timaeus* 53c–56c.
68. Reference unclear.

continuous with something spherical is spherical. And it is the same way with what is at the center of these spheres; for it is necessary for the things circumscribed by things spherical, and in contact with them as wholes, to be spherical. But the things below the sphere of the planets are in contact with the sphere above them. So all of them would be spherical;[69] for everything is in contact and continuous with the spheres.

Further, since the universe appears and is assumed to revolve in a circle, and it has been proved[70] that there is neither void nor place outside the outermost revolution, it is also necessary, because of these things, for it to be spherical. For if it is rectilinear,[71] the result will be that there is space, body, and void outside it. For something rectilinear, turning in a circle, will never occupy the same space, but rather where previously there was body, now there will not be, and where now there is not, there will be one again, because of the changing position of the angles.

Similarly, even if it were to be some other shape not having equal lines from the center—for example, lentil-shaped or ovoid; for in all instances it would result that there is place and void outside its spatial movement, because the whole does not occupy the same space.

Further, if the spatial movement of the heaven is the measure of movements because only it is continuous, regular, and eternal, and what is least in each thing is its measure, and if the fastest movement is the least, it is clear that the movement of the heaven would be the fastest of all movements. Moreover, the line of the circle is the least line from a point to itself,[72] and the fastest movement is that along the shortest line. So if the heaven spatially moves in a circle and moves fastest, it is necessary for it to be spherical.

But it is also possible to obtain this conviction from the bodies situated around the center. For if water surrounds earth, air water, and fire air, the upper bodies will also be in the same ratio (for though they are not continuous with them, they are in contact with them). But the surface of the water is spherical, and what is **$287^{b}1$** continuous with what is spherical, or is situated surrounding what is spherical, is necessarily so itself. So it would also be evident from this that the heaven is spherical.

But then that the surface of the water is like this is evident to those who take it as an assumption that water is naturally such as always to flow into what is more hollow. And what is more hollow is what is closer to the center. Let, then, the lines AB and AC be drawn from the center, and let them be joined by the line BC [Fig. 11]:

69. Reading ὥστε σφαιροειδῆ ἂν εἴη πάντα.
70. $279^{a}11–18$.
71. I.e., a polyhedron.
72. Reading ἀπὸ τοῦ αὐτοῦ ἐπὶ τὸ αὐτὸ.

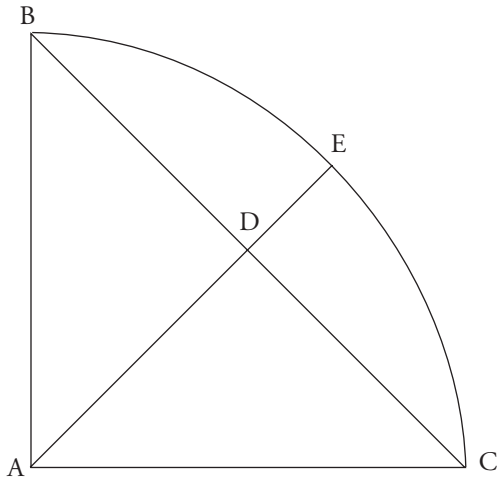

Fig. 11

The line AD drawn from the base is less than the ones from the center [AB and AC]. Therefore, the place is more hollow. So let water flow around until it is equalized. But AE is equal to those from the center [AB and AC]. So it is necessary for the water to reach [the ends of] the lines from the center [B, E, and C]; for then it will rest. But the line in contact with [the ends of] those from the center is the circumference. Therefore, the surface BEC of the water is spherical.

That the cosmos is spherical, then, is clear from these considerations, and that it is rounded so exactly that nothing artificial, nor anything else that appears within sight of our eyes, comes close to it. For none of the things from which it gets its composition is capable of receiving a regularity and exactness in the way that the nature of the all-around body is; for it is clear that they have a proportionality: as water is to earth, so it always is too with the more distant of the co-ordinate ones.

2.5
Why the Primary Heaven Revolves in One Direction Rather Than the Other

There are two ways of moving in a circle—for example, from A to B and from A to C; that these movements are not contraries was said previously.[73] But if nothing that is by luck or by chance can possibly be among the eternal things, and the heaven is

73. 271a19–22 (Fig. 4).

eternal, as its spatial movement in a circle, due to what cause does it spatially move in one direction and not in the other? For it is necessary for this either to be a starting-point or that there be a starting-point of it.

To try to prove all things, omitting nothing, in the same way as one does certain things, would perhaps seem to be a sign of great naivete or of great audaciousness. But it is not just, at any rate, to censure in the same way all [who do try]. Instead, one must look to see what the cause is of their saying what they say, and furthermore in what way they have hold of their conviction, whether in a merely human way or something stronger. Indeed, when someone hits on necessities that are more exact, then one must show gratitude to the discoverers; for now, though, we must state what **288^{a}1** appears to be so.

For if nature always produces the best of the things that are possible, and if, just as in the case of rectilinear spatial movements, that toward the upper place is more estimable (for the upper place is more divine than the lower), and in the same way too forward spatial movement is more estimable than backward, and[74] if indeed [the heaven] has a right and a left, as was said previously[75] (and the puzzle just stated testifies that it does), it has a priority and a posteriority; for this cause resolves the puzzle. For if things are in the best state possible, this would in fact be the cause of what was stated; for it is best to be moved with a simple, unceasing movement, and for this to be in a direction that is more estimable.

2.6
Why the Primary Heaven's Movement Is Regular Rather Than Irregular

As regards the movement of it, that it is regular and not irregular is the next issue that should be discussed. I mean this about the primary heaven and about the primary spatial movement; for in the lower [places] several spatial movements have already come together into one.

For if it moves irregularly, it is clear that there will be an acceleration, top speed, and deceleration of the spatial movement; for every irregular spatial movement has an acceleration, top speed, and deceleration too. And the top speed occurs either at the point from which a thing moves, at the point to which it moves, or at the mid-point—for example, perhaps for things spatially moving in accord with nature it is at the point to which they move, for those that move contrary to nature it is at the one from which they move, and for projectiles at the mid-point. Of spatial movement in a circle, on the other hand, there is no point from which, point to which, or mid-point; for of it there is simply neither starting-point, limit-point, nor mid-point; for

74. Reading ἔχει δέ.
75. 285^{a}31.

in time it is eternal and in length joined in one and unbroken. So if there is no top speed of its spatial movement, there will be no irregularity either; for irregularity comes about because of deceleration and acceleration.

Further, since everything that moves is moved by something, it is necessary for irregularity of movement to come about either because of the mover, because of the thing moved, or because of both; for if the mover did not move it with the same capacity, or if the thing moved alters and does not remain the same, or if both changed, nothing prevents the thing moved from moving irregularly. But none of these can possibly come about in the case of the heaven; for it has been proved[76] that the thing moved is primary, simple, incapable of coming to be, and wholly unchangeable. But it is much more reasonable for the mover to be like this; for the primary one is capable of moving the primary one, the simple one is capable of moving the simple one, and the one incapable of passing away and coming to be is capable of moving the one incapable of passing away and coming to be. Since, then, the thing moved, which is a body, does not change, neither will its mover, which is incorporeal, change. So it is also impossible for its spatial movement to be irregular.

For if it becomes irregular, either it changes as a whole and becomes faster at one time and slower again at another, or its parts do. But that its parts are not irregular is evident; for it would, in the unlimited time, by now have produced a difference in the distances of the stars, if one part were moving faster and another slower. But none of these distances is observed to vary.

But neither is it possible for the whole to change; for the deceleration of a given thing results from incapacity, and incapacity is contrary to nature; for in fact the incapacities in animals are all contrary to nature—for example, old age and wasting away. For presumably the whole composition of animals is made up of the sorts of things that differ in their proper places; for none of their parts occupies its own proper space.

If, then, among the primary things there is nothing contrary to nature (for they are simple, unmixed, and in their proper space, and nothing is contrary to them), there would not be any incapacity either, and so no acceleration or deceleration; for if there is acceleration, there is also deceleration.

Further, it is also unreasonable that the mover is incapable of doing so for an unlimited time, and capable of doing so again for another unlimited one; for nothing appears to be contrary to nature for an unlimited time (and incapacity is contrary to nature), nor contrary to nature and in accord with nature for an equal time, nor, in general, capable and incapable for an equal time. And it is necessary, if the movement decelerates, that it do so for an unlimited time. Moreover, neither is it capable of always accelerating nor again of always decelerating; for then the movement would be unlimited and indefinite, but all movement, we say, is from something to something—that is, definite.

76. 1.2–3.

Further, if someone assumes there is some least time, which it is not possible for the heaven to move in a lesser one than (for just as it is not possible to play the lyre or to walk in any time whatever, but rather for each action there is a definite least time which cannot be surpassed, so too it is not possible for the heaven to move in any time whatever)—if, then, this is true, there would not always be an acceleration of **289a1** movement (and if there is not acceleration, neither is there deceleration; for the same goes for both and each), if indeed it accelerates by identical or increasing increments of speed, and for an unlimited time.

It remains, then, to say that the movement is alternately faster and slower. But this is entirely unreasonable and like a fabrication. Further, if such were the case, it is also more reasonable that it not go unnoticed; for things put next to each other are easier to perceive.

About the fact that there is only one heaven, then, and that it is incapable of coming to be and is eternal, and further, that it moves in a regular way, let this much suffice for us.

2.7
The Stars

We should next speak about what are called "stars," what they are composed of, in what sorts of shapes, and what their movements are.

It is most reasonable, then, and follows from what we have said, to make each of the stars be composed of the body in which it has its spatial movement, since we said[77] that there is something that is of a nature to spatially move in a circle; for just as those who declare that the stars are fiery do so because they say that the upper body is fire, and that it is reasonable for each to be composed of what it is in, so we too are speaking in a similar way.

The heat and light from the stars come about when air is chafed by their spatial movement. For movement is of a nature to ignite even wood, stones, and iron. It is more reasonable, then, for it to do the same to what is closer to fire, and air is closer to fire—as, for example, in the case of spatially moving missiles; for these are themselves ignited to such an extent that lead balls melt, and, since these are ignited, it is necessary for the air around them to be affected in the same way. These missiles themselves, then, are heated up because of their spatial movement in air, which becomes fire because of a blow struck by the movement.[78]

Each of the upper things spatially moves in its sphere, so that, though they themselves cannot ignite, the air beneath the sphere of the rotating body is necessarily

77. 1.2–3.
78. *Mete*. 341^{a}17–31.

heated up, especially there where the sun happens to be fixed. That is why heat comes about when the sun gets closer, rises, and is over us.

About the fact that the stars are neither fiery nor spatially move in fire, then, let us say this much.

2.8
The Stars' Spatial Movement

289b1 Since both the stars and the whole heaven appear to change position, it is necessary for the change to occur either with both being at rest, both moving, or one being at rest and the other moving.

For both to be at rest is impossible, if the earth is at rest; for then the things that appear to be the case would not come about. And so let it be assumed that the earth is at rest. It remains, then, that both move, or that one moves and the other is at rest.

If, then, both move, it is unreasonable for the speeds of the stars and of their circles to be the same; for then each star will be equal in speed to the circle on which it is carried. For they appear to return to the same point at the same time as their circles. The result, then, is that a star has traversed its circle at the same time as its circle has carried out its own spatial movement in traversing its circumference. It is not reasonable, however, for the speeds of the stars and the magnitudes of their circles to stand in the same ratio. For it is not at all absurd—rather, it is necessary—for the circles to have speeds proportional to their magnitudes, but for each of the stars in them it is not reasonable at all. For either the star spatially moving in the greater circle will of necessity move faster, in which case it is clear that even if the stars were transferred to each other's circles, one will be faster and the other slower (in this way they would not have their own movement, but they would be carried by their circles). Or, if it happened by chance, it would still not be reasonable for it to happen in such a way that in every case the circle was greater and at the same time the spatial movement of the star on it was faster; for there is nothing absurd about one or two cases being this way, but for all alike to be so seems like a fabrication. At the same time too, luck is not found in things that are by nature, and what holds by luck is not what holds everywhere and in all cases.

But then again if the circles remain at rest while the stars themselves move, there will be the same unreasonable results, and in the same way; for the result will be that the outer stars move faster, and that their speeds are in accord with the magnitudes of their circles.

Since, therefore, it is not reasonable either that both move or that the star alone does,[79] it remains that the circles move while the stars remain at rest, and, fixed to their circles, are carried around; for in this way alone nothing unreasonable results;

79. Reading τὸ ἄστρον μόνον.

for [first] it is reasonable for the speed of the larger circle to be faster where the circles are fixed around the same center (for just as in the case of other things the greater body carries out its own proper spatial movement faster, so it is too in the case of bodies moving in a circle; for of arcs cut off by lines from the center, that of the greater circle is greater, so that it is reasonable for the greater circle [and the smaller one] to rotate in an equal time), and [second,] the result is, both because of this and because it has been proved that the whole is continuous,[80] that the heaven is not dispersed.

Further, since the stars are spherical, as others too say, and for us it is consistent to say, generating them as we do from that body,[81] and since of what is spherical there are two intrinsic movements, rolling and rotation, if indeed, then, the stars move because of themselves, they should move with one or other of these movements. But they appear to move with neither.

For in rotating they would have remained in the same place and not have changed it, which is precisely what they appear to do and everyone says they do. Further, it is reasonable for all of these to be moved with the same movement, but among the stars only the sun seems to do this in rising and setting, and it seems so not because of itself [rotating], but because of the distance from our sight; for sight, when extended a great distance, wobbles because of its weakness. This is precisely the cause too, perhaps, of the fixed stars appearing to twinkle, and of the planets not appearing to twinkle; for the planets are close by, so that sight reaches them while it is strong, but when it reaches the fixed stars, it shakes because of the distance, that is, because it is stretched out too far. And its trembling makes the movement seem to be the star's; for it makes no difference whether our sight moves or the thing seen does.

Moreover, it is evident that the stars do not roll either; for it is necessary for a thing that rolls to turn about, but the so-called face of the moon is always visible.

So, since it is reasonable that in moving because of themselves they move with their own proper movements, but they are not observed to move in this way, it is clear that they cannot move because of themselves.

In addition to this, it is unreasonable that nature gave them no instrument for movement (for nature does nothing by luck), and that it should care for animals, but overlook such estimable beings. Instead, it seems that nature, as if advisedly, excluded anything by means of which they could move forward by themselves, and that it set them at the greatest distance from things that have instruments for movement.

That is why it would also seem to be reasonable for the whole heaven and each of the stars to be spherical. For the sphere is the shape most useful for movement within itself (for as such it can at once move fastest and most of all occupy the same place), while for forward movement it is the least useful; for it is least similar to those things that move because of themselves; for it has nothing appended or projecting, as the

80. 287^{a}2–11, 287^{a}30–^{b}14.
81. I.e., ether.

rectilinear figure does,[82] but stands farthest apart from the shape of bodies that move by walking).

Since, then, it is necessary for the heaven to move with a movement within itself, but for the stars[83] not to move forward because of themselves, it is reasonable for each to be spherical; for most of all as such, the one will move and the others will be at rest.

2.9
No Harmony of the Spheres

It is evident from these considerations that the view that a harmony is produced when they [the heavenly bodies] spatially move, since their sounds are in concord, though stated in an extraordinarily subtle way by those who express it,[84] does not thereby have any truth to it. For it seems to certain people that it is necessary for a sound to be produced when such large bodies spatially move, since this happens even in the case of the ones around us, which do not have equal mass or spatially move with such a speed. But when the sun and the moon, and further, stars of such number and magnitude, spatially move with such speed, it is impossible for some sound, inconceivable in magnitude, not to be produced. Assuming these things, as well as that the speeds, based on the distances, have the ratios of musical concords, they say that, when the stars spatially move in a circle, the sound is in harmony. But since it seems unreasonable that we do not also hear this sound, they say that the cause of this is that the sound is present straight from our birth, so that it is not distinguishable from the silence contrary to it; for sound and silence are distinguished in relation to each other. So just as to coppersmiths, because of what they are accustomed to, sound and silence do not seem to differ, to human beings too the same thing happens.

These things, then, as was said earlier, are harmoniously and musically stated, but it is impossible for them to be this way. For it is not only absurd that nothing is heard (they do try to resolve[85] [the puzzle] about its cause), it is also absurd that nothing is affected apart from perception. For excessive sounds shatter the masses even of inanimate bodies—for example, that of thunder splits stones and
291ᵃ1 the toughest of bodies. With so many things spatially moving, and the sound passing through being proportional to the spatially moving magnitude, it is necessary for a magnitude that is many times greater to reach here, and for the strength of its force to be inconceivable. But it is reasonable [to conclude] that we do not hear it, and that bodies are manifestly not affected forcibly by it, because no sound is produced.

82. The projections or appendages are presumably the angles or edges of its faces, which are imagined as sticking out from the inscribed sphere.
83. Reading τὰ δ᾽ἄστρα.
84. Identified at 291ᵃ8 as Pythagoreans.
85. Reading λύειν.

At the same time the cause of these things is clear, and is witness to the truth of the accounts we have stated; for what puzzled the Pythagoreans and made them say that there is a concord in the moving things is a proof for us.

For whatever things are themselves in spatial movement produce a sound and a blow, while whatever things are fixed to or present in a spatially moving thing, such as the parts in a ship, cannot produce a sound, nor could the ship itself if it were carried along on the river. And yet it would be possible to come forth with the same arguments, saying that it is absurd if, when spatially moving, the mast and the stern of so large a ship do not make a great sound, or again the ship itself when it is spatially moving. But though when something spatially moves in something not spatially moving, it does produce a sound, when it is in, and continuous with, something spatially moving and does not produce a blow, it cannot produce a sound. So in the present case one must say that if indeed the bodies of the stars are moving either in a quantity of air or of fire spread through the universe, as everyone says, it is necessary for them to produce a sound of enormous magnitude, and if this happens, for it to reach here and shatters things. So, since it is evident that this does not result, none of the stars could be spatially moving with either an animate or a forced spatial movement, as if nature foresaw the future, namely, that if they did not have their movement in this way, nothing in the place around here would be the same.

That, then, the stars are spherical and that they do not move because of themselves, has now been stated.

2.10
The Stars' Order

As to their order—the way in which each moves, some being prior and some posterior, that is, how they are related to each other with respect to their distances—let a theoretical grasp be gotten on it on the basis of astronomical accounts;[86] for they speak adequately about it. And it turns out that the movements of each are in proportion to their distances, one lot being faster and the other slower; for since the outermost revolution of the heaven is assumed to be at once simple and fastest, while those of the others are slower and many (for each is carried on its own circle **$291^{b}1$** in a direction contrary to the heaven), it is reasonable immediately that the one closest to the simple and primary revolution traverses its own circle in the longest time, the furthest away in the shortest, and in the case of the others, always the closer in a longer time, the further away in a shorter one. For the closest is most of all controlled by the primary locomotion, the furthest away least of all, because of the distance, and the intermediate ones in proportion to the distance—as the mathematicians also prove.

86. *Met.* 12.8.

2.11
The Stars' Shape

The shape of each of the stars one would most reasonably assume to be spherical. For since it has been proved[87] that they are not naturally such as to move because of themselves, and nature produces nothing unreasonably or pointlessly, it is clear that it also gave to these unmoving things a shape that is least capable of movement. But the sphere is least capable of movement because it has no instrument for movement. So it is clear that the stars will be spherical in mass.

Further, it is similarly so for one and all. The moon, on the other hand, proves itself to be spherical by the evidence of sight; for otherwise it would not be mostly crescent-shaped or gibbous in the greater part of its waxing and waning, and only at one time semicircular. And, again, [it is proved] through astronomy that the eclipses of the sun would not be crescent-shaped [if the moon were not spherical]. So if indeed one star is like this, it is clear that the others too would be spherical.

2.12
Two Puzzles about the Stars' Movements

There are two puzzles, which it makes perfect sense for anyone to puzzle over, about which we must try to state what appears to be so, thinking such audaciousness to be reverence rather than rashness, if someone, because of his thirst for philosophy, is content to become a little more puzzle-free concerning the things about which we have the greatest puzzlement.

Among the many things of this sort, not the least wondrous is what the cause is due to which it is not those bodies that are more distant from the primary spatial movement that always have more movements, but rather that the intermediate ones have the most. For it would seem reasonable, since the primary body has one spatial movement, for what is closest to it to move with the fewest movements—for example, two, the next three, or that there be some other order of this sort. But as things stand, the contrary is the case; for the sun and the moon move with fewer movements than some of the wandering stars.[88] And yet these are further away from the center and closer to the primary body. And in some cases this has even been made clear by sight; for we have seen the moon, when half-full, move under the star of Ares [Mars], which was occulted by the dark half of the moon, and come out on its light and bright side.[89] The ancient Egyptians and Babylonians, who have kept a close watch

87. 2.8.
88. *Met.* 10.8 explains.
89. Dating the sighting to May 4, 357 BC between 7:49 and 8:00 p.m. ± about 1,000 seconds, Athens mean time.

for the most years, speak similarly about the other stars as well, and from them we have acquired many convictions about each of the stars.

One might justly raise this puzzle and also that of what exactly the cause is due to which the multitude of stars in the primary spatial movement is so great that their whole order seems to be uncountable, while each one of the other stars is separate, and two or more do not appear fixed on the same spatial movement.

As regards these issues, then, it is well to seek to increase our comprehension, even though we have few things to start from and are at such a great distance from what happens concerning them. Nonetheless, for those who get their theoretical grasp on the basis of things of the following sort, what is presently puzzling would not seem to be at all unreasonable. We think about these stars as bodies only, that is, as units having a certain order, altogether inanimate. But we should conceive of them as if they participated in action and life; for in this way what happens will not seem at all contrary to reason. For it seems that the good belongs without action to what is in the best state, to what is closest by means of one small action, and to what is further away by means of several actions. It is just as in the case of the body: one is in a good state without exercising, another by walking around a little, a third needs running, wrestling, and hard training, while to another again this good would not yet belong no matter how much exertion he undergoes, but rather a distinct one.

It is difficult to attain success either in all things or often—for example, to make ten thousand Chian throws at knucklebones is inconceivable, but one or two is comparatively easy.[90] And, again, when it is necessary that one do this for the sake of that, and that for the sake of something else, it is easy to succeed at one stage or two,[91] but when it is through a greater number, it is more difficult.

That is why one should think the action of the stars to be like that of animals and plants. For here the actions of human beings are in fact most numerous; for it is possible to attain many goods, so that it is possible to do many things in action, and for the sake of other ones. (What is in the best state, by contrast, has no need of action; for it is itself the for-the-sake-of-which; but action is always in two [varieties]: when it is the for-the-sake-of-which and when it is what is for the sake of that.) The actions of the other animals, on the other hand, are fewer, and of the plants perhaps one small one; for either there is some one thing which they may attain, as there is for a human being too, or all the many things are a route toward the best one. One thing, then, has and participates in the best, one reaches close[92] to it by means of few [steps], another by means of many, and another does not even try, but it is sufficient for it to come close to the ultimate [end]. For example, if health is the end, one thing, then, is always healthy, another is healthy after slimming down, another after running and slimming down, another after doing some other action for the sake of running, so

90. The equivalent of throwing ten thousand double sixes at dice.
91. Reading ἑνὶ καὶ δυσὶ.
92. Reading ἐγγὺς.

that its movements are more numerous; a distinct one, though, is incapable of getting closer to being healthy, but only to running or slimming down (and one or the other of these is the end for them). For, on the one hand, it is best of all for each to attain the end; but on the other, if this is not [possible], it would always be better to the degree that it got closer to the best one.

And this is why the earth does not move at all, and things close to it have few movements; for they do not reach the ultimate [end], but as far as is possible attain the most divine starting-point. The primary heaven, however, attains this directly by means of a single movement. But the bodies intermediate between the first and the last ones, though they do attain it, do so by means of more movements.

As to the puzzle that in the primary spatial movement, though it is one, a great number of stars is involved, while each of the other stars has separately received its own movement, one might reasonably think that this holds primarily because of one thing; for one should understand that in the case of each one's life and starting-point the primary one has a great superiority over the others, and this superiority would turn out to be proportional; for the primary movement, though one, moves many divine bodies, while the others, though many, each moves only one; for any one of the planets spatially moves with several spatial movements. In this way, then, nature both equalizes things and produces a certain order, having given many bodies to the one spatial movement, and many spatial movements to the one body.

And further, it is because of this that the other spatial movements have one body, namely, that the spatial movements before the final one, which has one star, move several bodies; for the final sphere is carried fixed on many spheres, and each sphere is a body. The work of this final sphere, then, would be common [to all of them]; for while each sphere has a spatial movement that is by nature special to it, the other spatial movement is, as it were, added on; besides, the capacity of every limited body is related to a limited one.

About the stars spatially moving with circular movement, it has been stated what they are like with respect to their substance and with respect to their shape, as well as with regard to their spatial movement and order.

2.13
The Earth (1)

It remains to speak about the earth, where it is situated, whether it is among things at rest or things moving, and about its shape.

About its position, then, not everyone has the same belief, but most people say that it is situated at the center (as do all those who say that the whole heaven is limited). But the Italian thinkers, the ones called "Pythagoreans," say the contrary;[93]

93. In particular, Philolaus of Croton, A16–17 DK.

for they say that at the center there is fire, and that the earth, which is one of the stars, spatially moves in a circle around the center to produce night and day. Further, they establish another earth opposite to this one, which they call by the name "anti-earth," not seeking their accounts and causes with an eye toward the things that appear to be so, but rather dragging the things that appear to be so toward certain of their accounts and beliefs, and trying to cosmeticize them to make them fit.

Many others[94] might believe along with them that one should not assign the region of the center to the earth, but their conviction is based not on looking at the things that appear to be so but rather on arguments. For they think that it is fitting for the most estimable region to belong to the most estimable thing, that fire is more estimable than earth, the limit than the intermediate, and that the extremity and the center are limits. So analogizing on the basis of these considerations, they think that the earth is not situated at the center, but rather fire is.

Further, the Pythagoreans, at any rate, also because it is most fitting that the most controlling [element] of the universe be safeguarded, and the center is like that, name the fire that occupies this region "the guard of Zeus"—as if center were said unconditionally, and the center of its magnitude were also the center of the thing and of its nature! And yet, just as in the case of animals the center of the animal and of its body are not the same,[95] one should rather suppose it to be this way too in the case of the whole heaven. Due to this cause, then, there is no need for them to be disturbed about the universe, nor to introduce a safeguard at the center; instead they should seek that [very] center, what sort of thing and where it naturally is. For that center is a starting-point and is estimable, while the center of the place is more like an ending than a starting-point; for the center is what is determined, the limit what determines. And what encompasses, that is, the limit, is more estimable than what is limited; for the second is matter, but the first is the substance of the composition.

About the place of the earth, then, some hold this belief, and things are similar in the case of its immobility and movement; for not everyone conceives of them in the same way. Rather, those who say that it is not situated at the center say that it moves in a circle around the center, and that not only the earth does so, but also the anti-earth, as we said previously.[96]

Some people[97] even believe that several bodies of this sort may spatially move around the center, invisible to us because of the interposition of the earth. This, they say, is also why eclipses of the moon are more numerous than those of the sun; for each of the spatially moving bodies, and not only the earth, blocks it. For since the earth is not the center, but is distant from it by a whole hemisphere, they think that even if we do not dwell at the center, there is nothing to prevent things from

94. Probably Platonists, whom Aristotle often criticizes for being too fond of argument and too neglectful of perceptual evidence.

97. Certain Pythagoreans.

appearing in the same way as they would if the earth were at the center; for even as things stand nothing makes it clearly visible that we are at a distance of half a diameter from the center.

Some people also say that the earth, which is situated at the center, winds—that is, moves—around the pole stretching through the universe, as is written in the *Timaeus*.[98]

There is much the same dispute concerning its shape. Some believe that it is spherical, some that it is flat and drum-shaped.[99] The latter produce as proof that, in
294a1 setting and rising, the sun appears to make the part concealed by the earth a straight line rather than a curved one, while if indeed the earth were spherical, the line cutting it would have to be curved. But these people do not take into account the distance of the sun in relation to the earth and the magnitude of its circumference, which, on the apparently small circles [of the sun on the horizon], appears straight from far away. They should not be unpersuaded, then, because of this appearance, that the mass of the earth is circular. But they add something further and say that because of its being at rest it is necessary for it to have the shape it does.

For in fact, of course, about the movement and immobility of the earth people have spoken in many ways. It is necessary, then, for a puzzle to strike everyone; for thought must be pretty anesthetized not to wonder how exactly a small piece of earth, raised up high and released, spatially moves and is unwilling to remain at rest, the larger always doing so faster, while if one were to raise the entire earth up high, it would not spatially move. But as things stand, heavy as it is, it is at rest. Moreover, even if, when its parts are spatially moving, one removed the earth from below them before they had fallen, they will spatially move downward if there is nothing resisting.

So it makes perfect sense that the puzzle became a philosophical issue for everyone. But one might wonder why the resolutions of it do not seem more absurd [to people] than the puzzle. For because of the considerations we mentioned some, such as Xenophanes of Colophon, say that what is below the earth is unlimited, saying that it is rooted in the unlimited, in order not to have the task of seeking the cause.[100] That is also why Empedocles chastises them in the way he does, saying:

> If the depths of the earth and plentiful ether are unlimited,
> Like the words spoken pointlessly by the tongue of many
> Mouths are poured out, of those who have seen little of the universe.[101]

Some say that the earth is situated on water. For this is the most ancient account that has come down to us, stated, they say, by Thales of Miletus, on the supposition that the earth remains at rest because it floats like a piece of wood, or something else

98. 40b–c.
99. E.g., Leucippus (A26 DK).
100. B28 DK.
101. B39 DK.

of this sort (for in fact nothing of this sort is naturally such as to remain at rest on air, but on water)—as if the same argument did not apply to the earth and to the water supporting the earth; for water is not of a nature to rest when raised up high either, but rests on something.

Further, just as air is lighter than water, water is also lighter than earth. So how is **294ᵇ1** it possible for a lighter thing to be situated below one that is heavier in nature?

Further, if indeed the whole earth naturally remains at rest on water, it is clear that each of its parts will too. As things stand, it is evident that this does not happen, but rather any random part spatially moves to the bottom, and the bigger one faster. 5

These people seem to inquire up to a certain point, but not as far as it is possible to take the puzzle. For it is customary for all of us to make our inquiry not with an eye to the thing at issue but with an eye to the person who says the contrary; for a person even inquires within himself up to the point at which he is no longer able to argue against himself. That is why a person who is going to inquire well must be capable of 10 objecting by means of objections proper to the relevant kind, and this comes from having a theoretical grasp on all the differences.[102]

Anaximenes, Anaxagoras, and Democritus say that the cause of the earth's remaining at rest is its flatness. For it does not cut the air below it but sits on it like a lid, which is precisely what bodies that are flat appear to do; for these bodies even have 15 difficulty being moved by the winds because of the resistance. They say that because of its flatness the earth does the same thing in relation to the underlying air (which, not having enough room to change its place, is at rest because of the mass [of air][103] below it), just like the water in clepsydras. And they state many proofs that air, when 20 it is cut off and remains at rest, is capable of bearing great weight.

First, then, if the shape of the earth is not flat, it cannot be because of its flatness that it is at rest. And yet, from what they say, the cause of its immobility is not flatness, but rather magnitude; for because of a lack of space, the air, not having a way 25 out, remains at rest because of its being large in quantity; and it is large in quantity because it is enclosed by the large magnitude of the earth. So, this would be the case even if the earth were spherical, but its magnitude were just as great; for according to their argument it will remain at rest.

In general, our dispute with those who speak in this way about the movement 30 of the earth is not about parts, but about a certain whole and totality. For one must determine at the start whether bodies have a certain movement by nature or none, and whether though by nature there is none, by force there is. But since determinations have been made previously about these matters,[104] as far as was in accord with the capacity that was at our command, we must use them as things **295ª1** taken for granted.

102. *Top*. 105ª21–25.
103. Reading ἀθρόῳ τῷ.
104. 1.2, *Ph*. 5.6.

For if they have no movement by nature, nor will they have one by force; and if there is neither one by nature nor by force, there will be no movement at all; for about these matters it was determined previously[105] that this result is necessary, and in addition that rest is not possible either; for just as movement belongs either by force or by nature, so too does rest.
